ABSTRACT

The Circulation of Money in Roman Britain from the First to Third century by John Creighton

"Any analysis of the ancient economy that pretends to be more than a mere antiquarian listing of discrete data has perforce to employ models"

Moses Finley The Ancient Economy

This thesis develops and employs models with the specific intention of trying to reconstruct an impression of how money circulated in Roman Britain in the first three centuries AD. The models are self standing and are potentially applicable to a wide variety of numismatic material, and also to other forms of material culture.

The work is divided into three parts. In the first the nature of the evidence from coin hoards is assessed. Using the weights of the coins, and analyses of the structure of the hoards, conclusions can be drawn about the changing velocity of circulation of coin at different dates, about its entry points into circulation, and about the division of wealth within society. The section uses a corpus of coin hoards from Britain which is provided in an appendix.

The middle part draws in the evidence from site finds. A model is created which combines site find and hoard evidence to attempt to reconstruct an idea of the changing money supply of Britain. This is done for both *denarii* and *sestertii* . The model is tested against a variety of data.

In the final section, a variety of other forms of evidence are drawn in to discuss broadly chronologically the changing nature of the circulation of money in Britain from the first to third century AD. The transition from Iron Age to Roman coins is analysed paying particular attention to the case of the Iceni. The relationship between the use of silver and 'bronze' coins is investigated, the debasement of the *denarius* and its replacement by the '*antoninianus*' is discussed. Finally the quantity theory of money is applied to the data, and the numismatic information is contrasted with that from other branches of archaeology.

The Circulation of Money in Roman Britain from the First to Third century

Preface

This thesis was made possible by the grant of a Durham University Studentship and a British Academy Award. Throughout I was supervised by John Casey. Frequent consultations over numerous cups of coffee and the occasional bottle of wine were always enjoyable. This thesis owes much to John who allowed me free reign to follow my own nose into areas which other supervisors might have discouraged. Also, for a thesis conducted so far from London, his own personal library proved invaluable. I have a lot to thank him for, and am glad to take this opportunity so to do.

The final stages of this work took place with the assistance of the Leslie Brooks Fellowship at St. Cuthbert's Society, with rooms provided just above the Society's wine cellar. I found it a most agreeable fellowship. More recently employment by King Alfred's College Winchester and Reading University has sustained me.

Throughout the years many people have contributed to this work. Some by reading through drafts, others by chatting over a bottle of wine or by providing me with opportunities to talk. I would like to thank the following: 'Chip', Jeremy Evans, Mike Fulford, Colin Haselgrove, Simon Keay, Tony King, Martin Millett and Richard Reece. The list is by no means exclusive. In particular I would like to thank Richard Brickstock whose keen attention to numismatic details and English grammar has benefited this work enormously.

I would like to single out the work of several people. Many of the ideas here first germinated when putting together a seminar paper as an undergraduate at Durham in 1984. I had to read through many of Richard Reece's papers, and I began to think about the limits of numismatic evidence. Some of the sections in here are the logical developments of ideas born back then.

None of this work would have been possible without the numerous numismatists who have catalogued hundreds of thousands of coins over the years; and those who have started to bring the data together in the form of corpora. I would like to single out Nick Ryan's work on site finds and Mike Sekulla's unpublished work on Northern coin hoards, both were invaluable to me. Just as important as the identifications are coin analyses, and here the late David Walker must be mentioned. The foundations for the sections within on bronze coinage in Britain and the debasement of the *denarius* were clearly laid down by him.

One person whose work I have deliberately ignored has been Chris Going's. There is a congruence of interest between one of the closing themes of this thesis (4.5) and the

work Going has been doing on pottery production cycles in Roman Britain. This emerged after a chance meeting in the Institute of Archaeology followed by far too many beers on an empty stomach. A manuscript copy of a paper by him arrived just as the final changes to this thesis were being drafted, too late to be incorporated properly. There are many similarities in our views and yet important differences as well. That remains as something to explore in the future.

There are bound to be mistakes which remain in any work as large as this, despite other people's help in tracking them down and eliminating them. They are of course all my own fault.

Finally I must thank my parents for their support over the years.

1.0 An Introduction

1.01 Economic data and Roman Britain

> "...the Romano-British economy has left us almost totally deficient in reliable statistics. That alone would make most modern methods of studying economic life inapplicable. We are, moreover, dealing with a world that, though highly sophisticated, worked in such a different way from our own that many commonplaces of modern economies are largely irrelevant... it is probably fruitless to seek to understand the underlying working of the ancient economy."
>
> (Salway 1981, 617)

If I had one principle aim in writing this thesis then it was to dispel the pessimism aired by Salway above. There are few literary references to 'economic life' in Britain in comparison to the heartland of the Roman Empire, and yet the by-products of that social and economic system, the archaeology, has probably been studied far more intensively in Britain than in any other province. However, archaeology has not yet provided the facts, figures and statistics that Salway felt were required, though that is not to say it is not possible. This thesis is an explicit attempt to explore how much is possible. What can one say about the Romano-British economy, or more specifically its monetary economy?

Anyone who tries to reconstruct statistics for the economy of the ancient world is liable to be prone to wide margins of error. I have no doubt that this work suffers from that as much as any other, but I think that the attempt is worthwhile nonetheless. Perfect economic data simply do not exist even in the world today. Government facts and figures may be issued frequently, but that is not to say that they are accurate. Opposition parties feel obliged to dispute them, frequently with good foundation. Not only does this economic data get criticism from other politicians, but economists themselves can get decidedly fed up:

> "Financial markets everywhere twitch at each new revelation in an ever-widening range of official statistics on economic performance. Yet the figures themselves seem increasingly foggy, with balances of payments that do not balance and national accounts that do not add up. ... Are all countries' statistics equally dodgy? ... Italy is widely thought to have the worst. International statisticians have still not forgiven it for adding an extra 18% to its GDP overnight in 1987, which just happened to push the size of its economy ahead of Britain's."
>
> (The Economist, no.7723, 1991, p 114)

So when I look back at the ancient historical world with its partial data liable to wide margins of error, comprising exaggerations, figments of rhetoric and maybe even the odd gross inexactitude, somehow things do not seem so different from today.

In studying the Romano-British monetary economy what information do we have at our disposal? In the realm of financial records the answer is very little. What appear to be accounts have been found amongst the tablets from Vindolanda, but whether they represent anything other than notional transactions of money within the confines of the Roman army's internal accounting system is unsure (Birley 1990). Few inscriptions have any prices on them, and when they do they are not particularly helpful (RIB 215, 274, 754 and 899). The most informative comes from a statuette of Mars found in the Foss Dyke in Lincolnshire. It stated that it had cost of 100 HS to make with the three *denarii* for the bronze donated for by the smith (RIB 274). However, one price is not going to tell us much about the economy of a country. Little help is obtained looking overseas for parallels. Most of the prices recorded in Italy and North Africa are for marble statues rather than bronze statuettes, so comparisons are difficult (Duncan-Jones 1982). Beyond a couple of literary references to the province the only other evidence we have comes from coins, and it is to these that the attention of this thesis primarily turns. If monetary information is to be reconstructed for Britain then it has to draw upon the creation of models based upon numismatic and archaeological data.

1.02 Coins and Archaeologists

In March 1973, a two day discussion was held at the Institute of Archaeology in London. The volume which evolved from it tried to close the growing gap between numismatics and archaeology (Casey & Reece 1974). All the papers contained within were concerned with 'applied numismatics'. The collection reflected the state of the subject at the time: What had been done so far? Where was the subject going? A number of themes kept on cropping up: one of them was a pessimistic view of how much coins could legitimately tell us, and how numismatic data had been misused by field archaeologists:

> "Several speakers expressed a feeling of despondency if not downright despair about the use of coins to archaeologists, especially their value as dating evidence. This despair came mainly from the archaeologists, but one suspects this is largely due to the expectation in the past of too much information from single coin finds."
>
> (Collis 1974b, 173)

> "This paper has been a plea for a realistic view of medieval English coins as dating evidence. Archaeologists want dating evidence which is certain and precise and when they find a coin they all too readily assume that they have got it. They rarely have."
>
> (Archibald 1974, 264)

One particular point which occurred in the majority of papers was coping with the longevity of coinage in circulation. It was not possible to create any simple rules about how long coins remained in circulation:

> "In normal circumstances a penny of 1250 found in a level of 1300 is certainly residual but a penny of 1300 found in a level of 1350 could very well be a contemporaneous loss as the coins of 1300 were among the commonest of those in circulation fifty years later."
>
> (Archibald 1974, 235)

This concern was by no means a new one. In his review of Romano-British archaeology in 1930 Collingwood referred to it being a major problem in dating (Collingwood 1930, 187). The only way which many of the authors thought they could tackle it at the time was by looking at the state of wear on the coin, though all professed a degree of unhappiness about this. Few considered wear to be a reliable guide to longevity. Different denominations circulated at different rates at different times. Many coins also lay idle in hoards for long periods of time. A number of suggestions were made during the discussions and Collis wrote an additional paper outlining some of his own ideas for tackling the problem (Collis 1974b). Unfortunately, more than ten years on, the preoccupations in the numismatic literature are still the same. In 1986 Casey still needed to say: "...the way in which many archaeologists have used, and are using, coin evidence is deplorable. Many discussions of sites are based on naive and erroneous assumptions rising from a profound ignorance of the problems which are inherent in numismatic studies." (Casey 1986, 68); and in 1987 Reece recounted a particularly depressing story of the problems of residuality (Reece 1987, 15-18).

The residuality of the coinage in the monetary system remains one of the major problems of applied numismatics and archaeology. Most material culture in Britain from the first century BC has been dated using associations with coinage. When it is considered that many Republican *denarii* were a couple of centuries out of date before they were lost, this can be worrying. The problem needs to be tackled as a matter of urgency if numismatic methodology is to develop. Some ideas have been put forward in articles such as Collis (1974b) and Crummy and Terry (1979), but the ideas have yet to be converted into usable numismatic tools.

1.03 The economy of an empire

Meanwhile in ancient history and other spheres of archaeology interest in the nature of 'the economy' grew throughout the 1970s and 80s. Two of the most influential works dealing with the Roman world were written by ancient historians. They were Moses Finley's 'The Ancient Economy' (1973) and Keith Hopkins' article 'Taxes and trade in the Roman Empire' (1980). Though Finley's work was largely restricted to historical

data, Hopkins paper was more interdisciplinary. Hopkins used many forms of evidence many would prefer to see as the preserve of archaeologists: shipwreck numbers, hoard structures, even population figures. Yet even these figures and some general statements about the levels of material culture understate the potential that the archaeological data can provide.

One of the main reasons that macro-economic studies have been slow to develop from archaeological evidence is the requirement for quantified groups of material distributed over a wide area. Many pottery and bone analysts have different ways of recording their data, and their lack of consistency hinders comparisons over any area larger than that which an individual can cover. Numismatics, however, has already overcome many of these problems. Though numismatists may still quibble over some identifications and attributions, there is now a tremendous degree of consistency in the recording of coinage. RIC and LRBC have become the standard catalogues, though occasionally references to other volumes still occur. This uniformity means that numismatics provides a tremendous potential data base spanning much of the Empire which has been reasonably consistently recorded.

What information does the paleoeconomist require? At present archaeology is divided into a variety of specialist fields. If it is going to reconstruct macro-economic models of the past then a large number of numeric variables are going to be required, each quantifying various aspects of Romano-British life. It would be perfectly possible to develop variables representing: the quantity of pottery from local, regional and overseas kilns found on sites; the amount of building activity (in the towns, small towns, villages and villa sites); the variety of produce grown on rural sites; and so on. Once such variables are established then it would be possible to see how changes in one area of Romano-British life effected other aspects. Such multi-variate models exist already for analysing more modern economic data, and similar methods have been used on anthropological data (Pryor 1977). Other variables could be derived from the literary and epigraphic record, such as estimates of the size of the standing army in Britain and its notional pay. As with all variables, limits of accuracy would be required.

Then there are a range of monetary variables which it would be interesting to relate to these. How much money was there in circulation and how evenly was this divided up? How quickly or slowly did it circulate? Where did it enter circulation? To what extent did society become monetized - was money progressively used for more and more things until the end of Roman Britain or did the monetary economy periodically expand and contract? All these questions appear to be impossible to answer directly, especially considering that fundamental variables like the residuality of coinage in the circulation

pool have yet to be worked out. All are questions about a dynamic system, whilst we only have its static remains left to exaimine.

Some people have already made such attempts to measure and compare some of these variables for the Empire as a whole. Crawford, on the basis of die-link studies, estimated the output of coinage in the late Republic. He then compared this figure to the total level of army pay during the period. The two plotted together (Crawford 1974, 697-707) showed a fair correlation down to the time of Sulla. On the other hand, Burnett (1987, Fig 5.1) attempted a similar analysis, this time comparing the army figures with the output of new coin as represented in the large Monte Codruzzo hoard. He managed to see only a very approximate correlation between the two. For the match to have been perfect would have required the army to have been paid only in new coin. Crawford believes that this was probably the case up until Sulla (Crawford 1974, 617-8), but after that the idea is harder to sustain. Indeed by 43 BC we have literary evidence for the reuse of old coin as payments by Octavian and Brutus (Crawford 1974, 640 n.2). In the same vein, Casey (1986, 123) compared Carradice's Domitianic output figures (Carradice 1983, 88-9) with the estimated level of army pay at the time. On average, the mint output only accounts for about 15% of the cost of the army. Even taking into account errors in the calculation of the output figures and the level of army pay, this difference is considerable. This is surely to be accounted for by the recycling of coin.

Hopkins (1980,106-9) tried to build an idea of residuality into his model of the money in the late Republic. Using Crawford's volume of output figures and making a number of assumptions about the data, he reconstructed a graph which purported to show the growth of the money supply during the late Republic; this he correlated with the idea of increasing trade. The following assumptions were used: "(a) either 30,000 coins were on average struck per (obverse) die, or the average number of coins struck per die was roughly stable throughout the period 157-50 BC; (b) the rate of loss was significant, and is here set tentatively at 2 per cent per year; (c) the initial stock of silver coins in 158 BC tentatively set at 35 million *denarii* ." Also he held that old coin was not reminted. Assumptions (a) and (c) are useful devices, they might prove to be inaccurate but they provide an order of magnitude and scale. The rate of loss from circulation, however, seems very high. Casey has suggested, from an analysis of finds at Corbridge and Caerleon, that only about 0.003 per cent of coins passing through a site get dropped and passed into the archaeological record (Casey 1986, 84-5). Even if the site lists only represent one hundredth of what there remains potentially to find, the 0.3 per cent still remains a whole order of magnitude different from Hopkins figure, though there are significant differences between the nature of Hopkins and Casey's analyses. But even if a growth in the money-supply was real (and setting a lower wastage rate would only

enhance this), the Empire had expanded as well during this period and the *denarius* had taken over from some pre-existing monetary systems in many of these areas. So if the increase in the money-supply was matched by a similar rise in the population using the coin then its net economic effect would be minimal. The lesson from this must be that monetary data must not be treated (and certainly interpreted) in isolation from other variables.

The one major problem with these kinds of studies ultimately based upon die-link analyses is that they only tell us (more often than not) about empire-wide phenomenon. The *denarius* circulated throughout the empire (with perhaps the exception of Egypt), by examining how many were produced will tell us about money-supply figures for the empire as a whole, but if our interest is on any lesser scale (such as the interaction between provinces) then this kind of analysis is not going to hold except in rare cases (such as the *Britannia* issues under Antoninus Pius). Also they cannot tell us about levels of Imperial expenditure since state payments may have been made in old coin as well as new.

1.04 Aims

> "...grousing is not good enough. Even in modern economic history, Fogel pointed out in a programmatic statement on econometric history, the 'new economic history', it "is often true that the volume of data available is frequently below the minimum required for standard statistical procedures. In such instances the crucial determinant of success is the ability of the investigator to devise methods that are exceedingly efficient in the utilization of data - that is, to find a method that will permit one to achieve a solution with the limited data that are available." For us there are very narrow limits: ... We shall see, however, that methods can sometimes be found by which to organize ancient data that appear beyond redemption at first sight."
>
> (Finley 1973, 25)

In what follows new numismatic models are developed with the explicit aim of trying to obtain monetary economic data for just one small area of the Roman World: Britannia. Above I posed a number of questions which one might wish to ask of the Romano-British monetary economy:

- How much money was there in circulation?
- How evenly was this distributed?
- How rapidly did it circulate?
- Where and how did coin enter circulation?
- Was monetization progressive or variable?

All of these questions and more are answered to some degree in what follows, and correlations with other historical and archaeological data are made. Some of the models

are more reliable than others and I hope that throughout I have made clear the reliability of the conclusions drawn.

The period chosen for the study has been the duration of the circulation of the *denarius* in Britain. Often the fourth century has received more attention because of the wild variation in the number of coins discarded in different periods; on all coin histograms the late third and fourth century always appears to be more dramatic than the tiny variations in the first and second century. Mint details and regional production provide the fourth century specialist with an extra avenue to explore which the High Empire monetary system does not really have. Nonetheless, the High Empire with its longevity of circulation of coin and its more subtle variation is perhaps an even harder testing ground for developing new models. Once developed and tested for Britain, hopefully these models will be suitable for use in other provinces and other coin series.

I am sure that as Finley said much of what follows may appear to be beyond redemption at first sight. However, I believe that much of it will sustain a second look.

Section 2: The Hoard

2.1 Historical and Conceptual Survey

First hoard typologies are reviewed (2.11), then the position of the hoard within the currency system pool is assessed (2.12). Two analyses are performed to try to clarify some of the ideas suggested about the nature of coin hoards (2.13-14), and finally the link between hoard structure and the nature of the circulation pool is discussed.

2.2 The Hoard Database

In this section the requirements of a hoard database are assessed (2.21). The hoard corpus is then introduced (2.22) with further comments about their structure and codification of the database (2.23 & 2.24).

2.3 Coin Wear and the Velocity of Circulation of Coinage

In this section the contribution that coin wear can make to reconstructing the circulation pattern of coinage is addressed. The work of Rogers and Duncan-Jones is examined where it is always assumed that the rate of wear did not vary (2.33). Learning the lessons from these analyses, a different way of looking at coin wear is attempted allowing for the chronological variation in rates of wear (2.34-36). In the light of this some of Duncan-Jones' work on the circulation of *sestertii* is reassessed (2.37).

2.4 Uniformity and Variability in Hoards

A broad pattern of similarity is found amongst British *denarius* hoards of the same date (2.41 & 2.42), however, this is not to say that their composition is entirely uniform. Reasons for variation in hoard structure are discussed (2.43), and contingency tables are used to see if this variability is consistent over time (2.44). It is not, and reasons are sought for this (2.45 & 2.46).

2.5 Hoard Structure

The aim of this section is to expand upon some of the ideas introduced in section 2.4. Here we want to examine in detail hoard structure. Two new methods are developed to quantify the structure of hoards (2.51 to 2.54). This information is then analysed for chronological (2.55) and geographical (2.56) trends; both of which are found.

2.6 Hoard Size

This section looks at the information to be derived from the size of hoards Three main questions are asked. Is there any difference between the structure of large and small hoards? (2.62) Is there any change in the relative numbers of big and small hoards through time? (2.63 & 2.64) And is there any geographical pattern to the distribution of abnormally large hoards in Britain? (2.65) But first the quality of the database is assessed (2.61).

2.1 Historical and Conceptual Survey

First hoard typologies are reviewed (2.11), then the position of the hoard within the currency system pool is assessed (2.12). Two analyses are performed to try to clarify some of the ideas suggested about the nature of coin hoards (2.13-14), and finally the link between hoard structure and the nature of the circulation pool is discussed.

2.11 Hoard typologies

Many hours of numismatic scholarship have gone into the creation of hoard typologies: emergency hoards, savings hoards, robber hoards, and other types of hoards, each expressing different motives for the accumulation and deposition of assemblages of coinage. These divisions are clearly expressed in Grierson's introduction to numismatics (Grierson 1975, 124-136). However, recently doubt has been cast upon the value of such distinctions. Kent (1974) repeated the standard typology while expressing reservations about many of the categories, whereas Crawford condemned the exercise as being of little validity and use: "One spectre that needs to be exorcised...is the obsession of much earlier scholarship with the classification of coin hoards according to the purpose of their depositors, a subject on which neither the ancient literary sources nor the circumstances of discovery of hoards shed much light." (Crawford 1983, 198). Reece expressed a similar viewpoint arguing that "anything which any archaeologist says about the circumstances surrounding a coin hoard can only come from his own head because it cannot come from the hoard" (Reece 1987, 47). To be fair, the occasional hoard exists which does 'speak' to us. One such was from Bollingen in Wurttemberg, buried in 1634 during the Thirty Years War. It contained a message saying that the Swedes were coming, taking everything into their possession, this hoard being all that the owner had left to protect (Grierson 1975, 132). However, such a case is the exception.

Since a debate exists about the value of these typologies, then this seems like a sensible place to start. The major classifications ascribed to hoards are as follows:

Emergency hoards:

> "It has, of course, long been recognized that the widespread concealment and loss of coin hoards, at a particular period, in a particular country or district, was, in all probability, due to unsettled conditions in that country or district. It has too, long ago been pointed out, notably by Sir George Macdonald, by Dr H. Mattingly, by Mr B. H. St. J. O'Neil, and by Dr C. H. V. Sutherland, that, in view of the probable connection between the loss of a large number of coin hoards and contemporary events, a study of the Roman coin hoards lost at various periods in Britain may be expected to throw light

> on contemporary Romano-British history, as well as, obviously, on contemporary Romano-British currency."
>
> (Robertson 1974, 14)

Such has been the historically dominated view of coin hoards, lots of hoards directly indicating warfare or troubled times (though this does not represent Robertson's view in totality). Leaving this questionable idea aside for one moment, what are the key points that a numismatist has to look for to distinguish an emergency hoard from any other type? The theorists suggest that special selection factors would not exist in the hoard, the collection being a corpus of whatever the collector could lay his hands on at the time he took fright. So 'emergency hoards' would represent a good idea of the money in circulation at the time of the crisis (cf. Grierson 1975, 133; Casey 1986, 54).

Savings hoards:

These Grierson described as being "hoards in the traditional sense - savings put together by their owners over a period of years" (1975, 135). We are expected to recognize these by the different set of selection criteria which determined their composition. It is suggested that they are selective, containing high value coins rather than low ones, and better specimens of such coins, some perhaps even unworn. Indeed because of all these complicated selection factors Grierson despaired of such hoards being much use in the reconstruction of the pattern of money in circulation: "It is probably the case that savings hoards are more useful to the modern scholar in supplying him with material than for any conclusions he can draw from their structure or incidence." (Grierson 1975, 135). Another suggestion is that if we look at the sequence of deposition of coins in a savings hoard, we might discover a chronological pattern. With the earlier coins at the bottom and the most recent issues at the top (Casey 1986, 55). This would only be the case in a hoard which had never been disturbed during its accumulation.

As can be seen, these ideas suggest that there would be a marked difference between the composition of emergency and savings hoards. Kent summarizes the argument:

> "The first group [emergency hoards], it is held, discloses a cross section of the available currency in the desired denominations at the date of deposition. Such hoards will reveal a gradation of wear from the earliest to the most recent coin. The second [savings hoards] results from careful men putting aside coins from time to time over a lengthy period; such hoards contain random peaks of material, corresponding to fluctuations in their collectors' prosperity, and do not show gradation of wear to the same extent."
>
> (Kent 1974, 185)

However, this nice distinction can become totally blurred as Casey points out: "...there is nothing to prevent a savings hoard being snatched from its domestic deposit place in a crisis and used to form an emergency hoard in some other location, but it would nearly be impossible to make this distinction in normal circumstances and the mere possibility of

such an event emphasizes the extreme difficulty and ambiguity of interpretation of hoard evidence." (Casey 1986, 56).

Robber hoards:

This kind of hoard presumably reflects stolen booty, in which case it seems difficult to see how it would differ from a savings hoard on analysis. Grierson however, points out that "...robber hoards can often be recognized by the presence in them of cut up silver plate as well as coin. Many date from the time of the Germanic invasions, two of the best-known having been found in the British Isles, at Coleraine in Ulster and Traprain Law in Scotland." (Grierson 1975, 132). However, the presence of hack silver together with coinage suggests that these might better be seen as collections of bullion, both recovered from areas beyond the Roman frontier. Surely what we have here is a difference in the function of coinage; that of money in the province and bullion beyond its frontiers. There is no necessity to resort to recourse to motives of dishonesty and Germanic invasions.

Abandoned currency hoards:

This category represents a collection of coins deliberately left unrecovered because the coins themselves had become demonetized by a currency reform. Often the numerous hoards of the Gallic Empire are assigned to this category in the belief that *antoniniani* were no longer legal tender after Aurelian's reform. A similar situation may have happened with the coins of Magnentius after his defeat in 353. Presumably these hoards would be typologically similar to savings hoards; though they would only occur in larger numbers at a time of dramatic change in the currency system.

Purse hoards.

These are meant to be small groups of coins, accidentally lost by the carrier, rather than deliberately hoarded away. Typologically they would be fairly small groups, possibly of mixed denominations and containing the smaller coins which do not usually occur in savings hoards. Their alleged importance is that they represent what 'the man in the street' was taking to market that day; in another words they "...show which coins were in contemporary use and for how long individual issues continued in circulation, so giving an index of the reliability for dating of individual coins found in archaeological strata." (Casey 1986, 57).

Other types of hoard:

These are the main descriptive categories used. Many variants on these themes exist, 'currency hoards' and 'circulation hoards' can often be used as terms to describe the

larger versions of 'purse hoards'. An example of one would be a shop-keeper's till found in a destruction deposit, such as the Minturno hoard (RRCH 98), lost in 191BC (Crawford 1983, 198).

Problems with 'emergency hoards'

However, as stated, such divisions have not met with universal approval. Much of the work done on the location and periods of warfare on the basis of 'emergency hoards' has met with a great deal of criticism and scepticism. When historical periods have been investigated, though there is often an increase in the numbers of hoards left in the ground, their geographical distribution rarely has a direct correlation with the location of the historical battlegrounds. Kent (1974) examined the hoards of the Civil War in the United Kingdom. He showed that the distribution of hoards during this period was certainly different from that of the preceding and following years. However,the 'war distribution' did not demonstrate any kind of relationship to the storm centres of the war; except for one small cluster around the garrison town of Newark (Kent 1974, 192). Grierson recalled the early seventh century in the eastern Mediterranean, where the overrunning by the Persians of the mainland led to numerous hoards occurring on the islands of Cyprus and Crete; presumably places of refuge rather than areas of action (Grierson 1975, 132). Finally Pepys' hoard was buried in Huntingdonshire; while the actual trouble which had stimulated its collection and deposition had taken place in the Medway (Casey 1986, 54). Clearly where we have supplementary historic information, the distributions of hoards are shown to be very spurious guides to actuality. Misuse of hoard data in less well documented periods is all too easy. The interpretation of Gallic Empire hoards in Gaul in the late third century by Blanchet (1900) is one such example. Gallic Empire hoards are much more frequent than hoards of the preceding periods, and historically there were 'barbarian incursions' attested in Gaul. Blanchet combined these two pieces of information, interpreting the distribution of hoards directly as the areas of disturbance. While seeming to be a logical procedure, this phenomenon of Gallic empire hoards also takes place in Britain, where no such incursions are recorded (for a critique see Reece 1981c). If historical cases are fraught with problems, woe betide us venturing with the idea into proto-historic periods. Grierson sounded a suitable warning of danger:

> "...numismatics have shown how hoards can often serve as guides to areas of military activity...."
>
> "...Where particular interpretations like troop movements are involved, however, we usually have to know about their existence first, either from other archaeological evidence or from documentary sources, and then show how the coin finds confirm them and add greater precision to the details. Too many alternatives are possible for it usually to be safe to base particular explanations on coin finds alone."
>
> (Grierson 1966, xi-xii)

If we question the merits of using 'emergency hoard' distributions as a method of quasi-historical reconstruction, then what of the actual initial classification of the hoards?

Problems with hoard typologies:

> "...past commentators have always started discussion of hoards of any date with ideas of savings hoards, emergency hoards, and purse hoards, and the different categories have to be drawn from the commentator's own mind since they preface any discussion of actual hoards, and the different categories have been fixed to different hoards with practically no justification."
>
> (Reece 1987, 61)

There is an important problem with these models of hoard construction. Since they are almost entirely drawn from the imagination of numismatists trying to reconstruct past human motives, hoards which fit into these preconceptions will neither prove or disprove the ideas without any other corroborative data, such as the note in the Wurttemberg hoard. Where testing has been possible such as with the location of civil war coin hoards, these preconceptions have proved unreliable. One must wonder how useful these distinctions are. After all, as Casey (1986, 56) pointed out, a savings hoard snatched in an emergency and buried, still, in the eyes of a numismatist, has the composition of a savings hoard. Crawford was highly sceptical about it all:

> "Classification of coins prior to hoarding, however, does not support the notion of a rigid distinction between 'circulation' hoards and 'savings' hoards. Seneca (*De vita beata* XXIV 2) talks of...'a hoard hidden away, which you would not bring out unless it were necessary'; and one may hypothesize that some of the hoards of which we know are of this type, consisting only of an accumulation of coins from which none has ever been taken away. At the other extreme lies a hoard such as the Minturno hoard (RRCH 98), the contents of a shopkeeper's till, lost in the fire of 191BC. Between these two extremes there is surely an infinite gradation..."
>
> (Crawford 183, 199)

Reece went even further by suggesting that "...if these divisions are worthwhile, then they ought to be visible in the hoards, which ought to divide up into different numerical groups." (Reece 1987, 61). Later in this section this proposition will be tested.

2.12 The place of hoards in the currency system

If we want to realize data from coin hoards, then we must examine their relationship to the circulation of money. The classic view of this is illustrated by Haselgrove's model (1987, 35), redrawn in fig. 21.01. Here coin hoards are seen as an appendage to the circulation of money, somewhere that coins can go and rest out of circulation for a while, before being recovered and doing the rounds of the market place again. Indeed the definition of hoard in this diagram is that of a concealed body of coinage. However, this gives a remarkably out-on-a-limb picture of hoards.

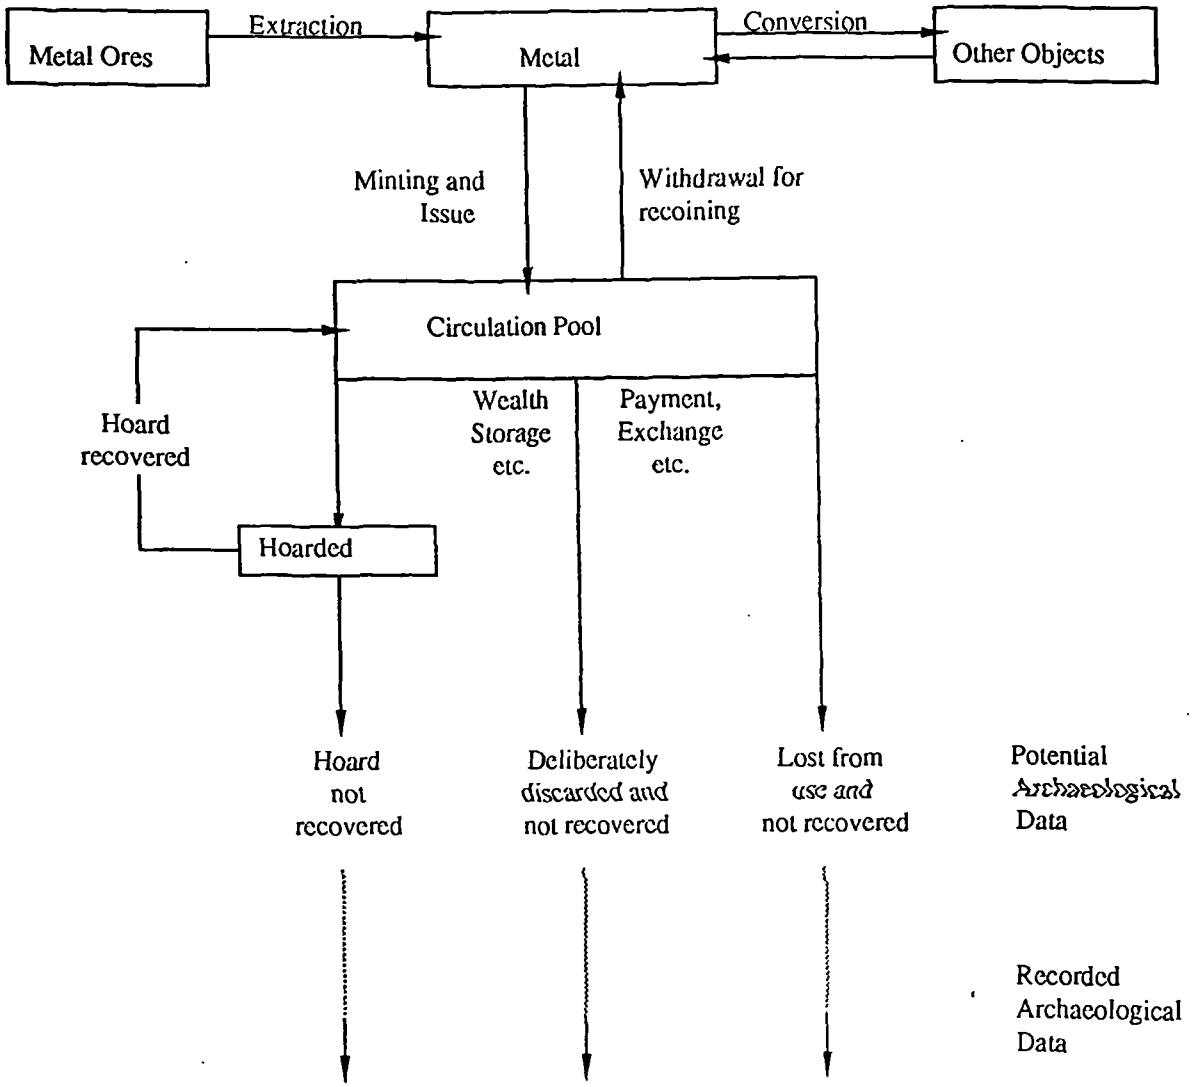

Fig. 21.01 Haselgrove's model of coin circulation

I would favour a less ethno-centric picture of circulation. In the present day, hoarding is a minimal activity because banking facilities exist. Our simple idea of the circulation pool consists of the coinage in our pockets, purses, in the till and perhaps the odd collection of 50p's for the meter at home. Coinage rarely hangs around at the bank, as the quantity received in and paid out each day usually balances fairly well. In antiquity, particularly Roman Britain, with its negligible evidence for any advanced banking facilities, the hoard of 50p's at home becomes much more significant. It becomes a dynamic store of wealth.

Collingwood pointed out that "...strictly speaking, coin is being hoarded whenever it is not being spent. The money in one's pocket, or in the till of a shop, is a hoard, even if none of it was there yesterday and none will be there to-morrow." (Collingwood 1930, 190). This view represents the hoard as a far more dynamic entity. This difference largely comes from a shift in emphasis in our terminology. Perhaps above ground we should refer to hoards as money-boxes, treasure-chests or cash-tills.

Robertson cites Cicero's *Pro Cluentio* (c. 179) which suggests that an *armarium* or money-chest was a familiar adjunct of a Roman household. This reference is by no means isolated in the classical literature. When the location of 'money' is mentioned, the most usual form is the triad of 'in land', 'out on an interest bearing loan' or 'in one's money-chest'. For example, Pliny in a letter about an Umbrian estate states: "You will ask whether I can easily raise the three million *sestertii* . Most of what I have is in land, but I have money out on loan and it will not be difficult to borrow. Besides, I can always have money from my mother-in-law, whose money-chest I can use as freely as my own." (Pliny, *Letters* , 3.19). Not to be out done, Trimalchio also had a money box, where he put ten million *sestertii* , because it could not be invested (*Satyricon* 54.3). Pliny, while in Bithynia, also had problems with investing money, and had to leave much lying idle in the city's money-chests (Pliny, *Epistles* 10.54). As Finley states: "This was a world which never created fiduciary money in any form, or negotiable instruments. Money was hard coin, mostly silver, and a fair amount of that was hoarded, in strong-boxes, in the ground, often in banks as non-interest-bearing deposits." (Finley 1973, 141) (though see section 4.52). We even have a description of some public hoards such as those in the temple of Apollo at Delos. In the strong room there were two treasuries, the 'sacred' and the 'public' chest. These consisted of a number of jars " on which was indicated the provenance of the contents or purpose for which it was earmarked" (Larson 1933-40, 341).

The 'circulation pool' is often talked about, but what in reality does it mean? It is all too easy to leave it as an abstract idea without contemplating the physical form that this media of circulating metal must have taken. The nature of the circulation pool can best be

contemplated by imagining life in Roman Britain suddenly frozen, with everyone stopped dead in their tracks. If we peer into this still frame and seek out the 'circulation pool', what would we find? A few coins might be in the process of being exchanged from one individual to another, a couple might be in flight as a coin is tossed to aid some decision-making process, slightly more might be in pockets being carried to or from market. But at any one time, the vast majority of coin would have lain in multiple individual accumulations or hoards.

The vast majority of silver coin would have lain in such deposits for most of their life-span; occasionally moving from one personal treasure-chest to another: via a hand, a purse, an exchange at the market or a payment to a tax official, and back into a money-box again - though this time someone else's. Smaller denominations, however, may tend to remain in the mobile purse or pocket, smaller numbers of which serviced and facilitated the exchange of larger denominations. With this image in mind I would redraw Haselgrove's diagram as fig. 21.02. As far as the circulation pool is concerned, the various denominations can be seen as spending unequal periods in different sectors of the hexagon, bronze coinage tending to stay to the left hand side, with precious metals to the right.

The next transformation to consider is the change from a collection of coinage in a money-box to becoming an unrecovered hoard available for us to find. The classic example of this transformation (though not the only one) is deliberate concealment. Robertson described a common motive, fear:

> "...a wealthy man who was about to set out on a journey and who feared either the dishonesty of those he left at home, or the hazards of the road, might conceal his treasure in a safer hiding place than his house until he returned."
>
> (Robertson 1974, 13)

Casey also suggested the same reason (Casey 1980, 53). This can be backed up, to some extent, by the classical literature. Robertson (1974,13) cited Plautus' play *Trinummus* , where a wealthy Athenian called Charmides did precisely this. Another sort of fear which has already been mentioned is that of warfare. Here we have the example of Cassius in Rhodes (Appian, *Historia Romana* iv, 73). In 42BC the people of Rhodes buried all their wealth in the ground on learning that Cassius was on his way; alas to no avail, since he made them dig it up again and surrender it all to him. Nonetheless, both are examples of temporary concealments.

The location of burial was of importance, it needed to be a memorable location, but not one that was entirely obvious or conspicuous. Pepys was incensed not only at finding his father had buried his savings in the garden during broad daylight (albeit on a Sunday

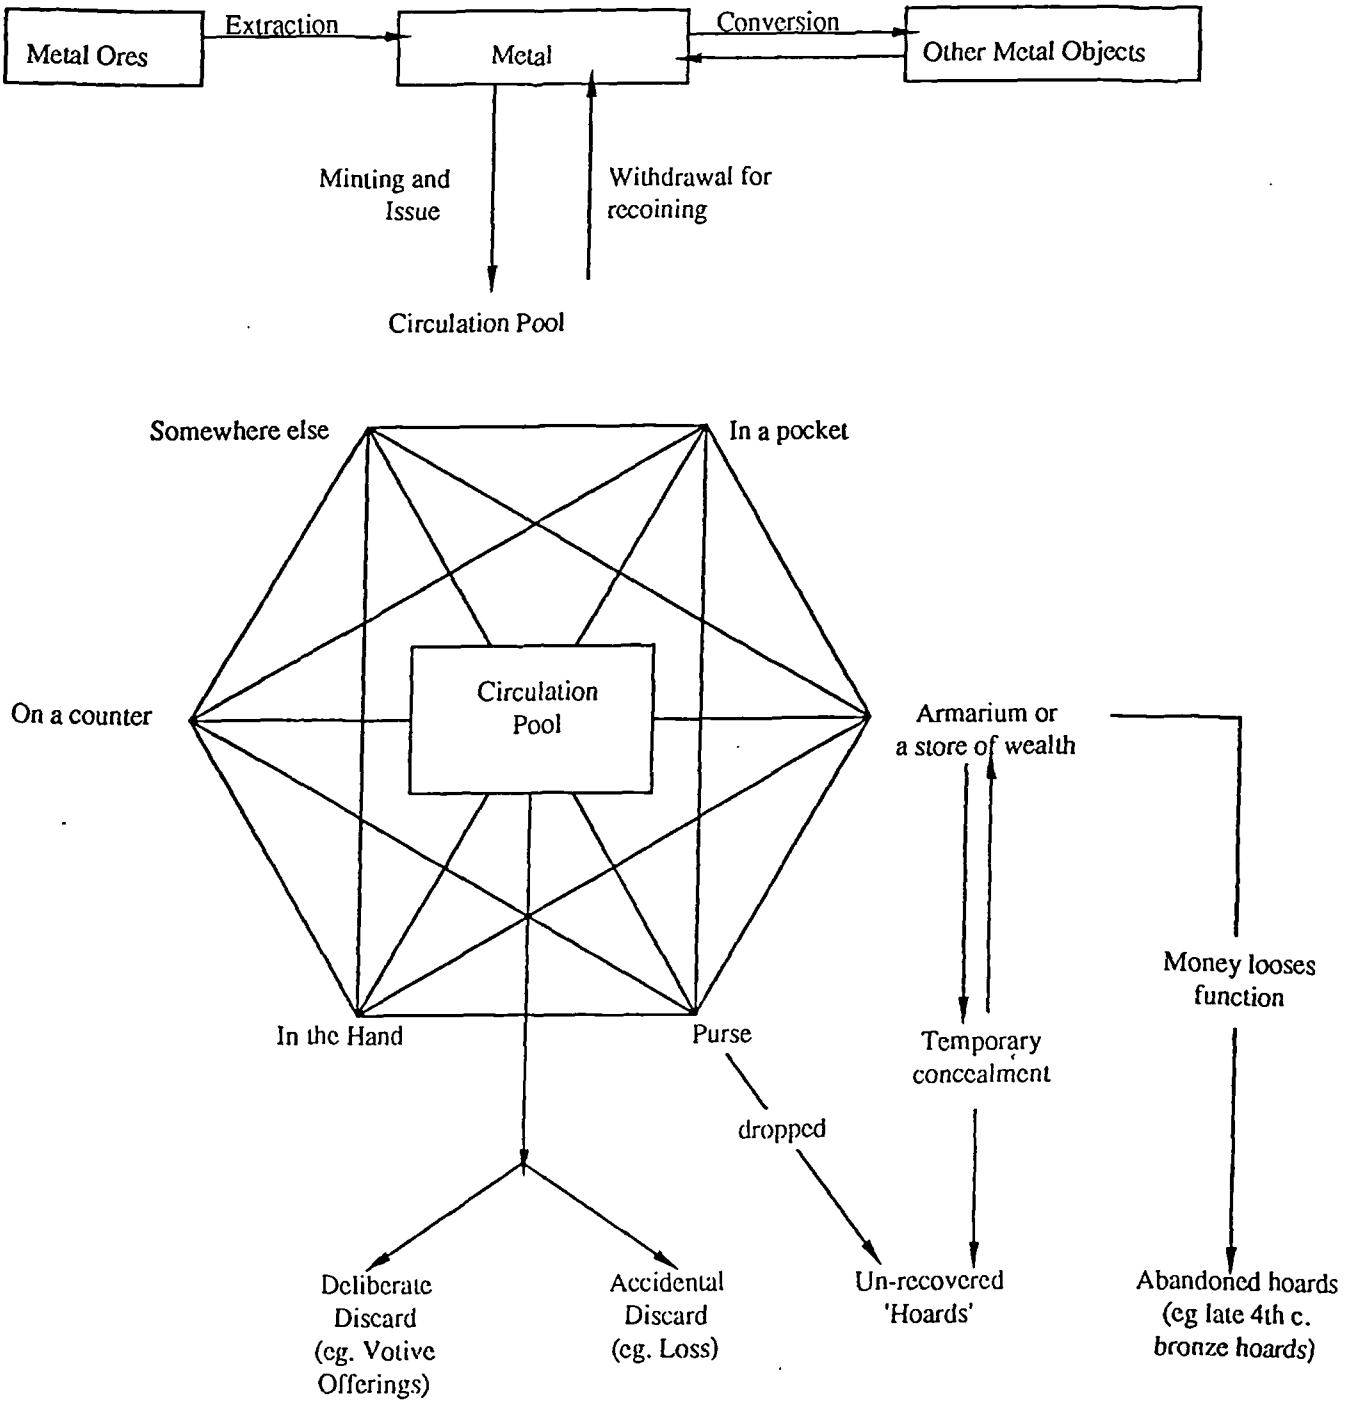

Fig. 21.02 Amended model of coin circulation

when everyone else was in church); but also that he had managed to forget where in the garden he had buried it. Robertson's study of hoards shows that the majority are found not on known settlement sites, but usually fairly nearby. However, there are exceptions:

> "Comparatively few hoards were deposited in inhabited sites, military or civil, and if they were, their position almost always shows that the owner took great care over their concealment - under the floor, in a hypocaust or pit, or in a disused ditch..."
>
> (Robertson 1956, 265)

This is the usual form of money-box to hoard transformation, and is directly expressed on fig. 21.02. The precise motive for concealment is unimportant here. However, there are other mechanisms. One case is that of abandonment hoards, where a currency has gone out of use. I do not intend to debate whether Gallic Empire hoards are such, since the sites of their concealment have not been noted to differ from the distribution of other hoards. However, this is not the case with late fourth century bronze hoards:

> "...it seems very likely that the hoard of copper coins lost, rejected or deposited after about AD 400, is the hoard most commonly encountered on Roman sites in Britain, (NB radiate hoards are far less commonly found on sites) and may eventually prove to be the most common type of Roman hoard. This would scarcely be surprising for it is the most obvious time when money might have been considered useless, hidden for 'the time being' and never recovered."
>
> (Reece 1974, 88)

In this case, the micro-distribution of hoards is different (at least in the south of England, though this may not be the case in the north, Casey pers. com.). The fact that the hoards are found on sites more frequently than before tells us a different mechanism is at work. Here it seems legitimate to assume the money simply lost its function. I would also wonder if it was particularly concealed, I would imagine that it simply remained where active money-chests were usually deposited in a household; whether that be in a pot on a kitchen shelf or under the floorboards. In our model of the system, the hoard would be created by a direct movement from the *armarium* to the archaeological record; not going via a concealment stage in the sense of earlier hoards.

Even though these transformation mechanisms are different, both can be seen as being family *armaria* without there necessarily being any differential selection processes having taken place prior to their deposition.

A third kind of transformation comes with the lost purse hoard. This is deposited from a different section of circulation pool. Many small collections may of course go unrecognized in site lists, as a leather bag may easily decay. On the other hand some may have been deliberate discards. At Birdoswald fort on Hadrian's Wall a purse hoard containing 28 *denarii* [S016] was found. It had been buried underneath the fort rampart.

It has been suggested that it was accidentally dropped just as the tons of rampart material were dumped on the bare earth site, and that once buried it was lost for ever. An alternative would be that it was some form of votive offering. Neither can be proved.

With our model, we have a large number of family *armaria* . As O'Neil says: "In the absence of organized banking facilities the practice of hoarding savings must have been well nigh universal in Romano-British times." (O'Neil 1935, 73). And in Robertson's view: "...unless the owner of a hoard was a miser, he must have been constantly taking money out of his savings, and again putting money in, or even spending his whole hoard and then starting to save afresh" (Robertson 1956, 268). This gives us a picture of the money-chest or unconcealed hoard, as being an important dynamic element of the currency pool. These ideas now need to be tested.

2.13 The micro-excavation of hoards

Earlier it was suggested that savings hoards might show chronological patterns in their make-up, with earlier coins being at the bottom, and later ones at the top. Conversely, if these were all dynamic collections of coin before deposition we would expect no such patterning to occur. Unfortunately this kind of analysis of a hoard is rare. Pots are often emptied out rashly in the excitement of the find. Nonetheless, at least five Romano-British hoards have been examined in this way. They are:

1.	Oliver's Orchard 1	[C 069]
2.	Oliver's Orchard 2	[C 070]
3.	Oliver's Orchard 3	[C 071]
4.	Aldbourne	-
5.	Tattershall Thorpe	[C 237]

The Oliver's Orchard Hoards:

> "The coins were...removed in batches according to the order in which they were removed from the pots, and it was possible to reconstruct an outline pattern of distribution within the containers. In hoards 1 and 3 the pattern was consistent, with the same mixture of coins in each layer within each pot. But in hoard 2 there was a noticeable difference in the balance between the earlier, finer coins and the later baser issues.
>
> ...it can be seen that the finest coins were concentrated in the upper part of the pot. At first sight this is rather surprising; it would seem to suggest that the contents of this pot were put together at the time of burial, with the fine coins, which had presumably been kept separate, being added at the end."
>
> (Bland and Carradice 1986, 65)

Hoards 1 and 3 showed a mixed structure, demonstrating that however the hoard had been gathered together, it had been actively mixed-up and used rather than slowly accumulated without ever being touched. Hoard 2 showed some patterning. The data (Bland & Carradice 1986, 70) has been drawn up, and is shown in fig. 21.03. Bland and Carradice made some inferences which cannot be derived from the hoard. We have

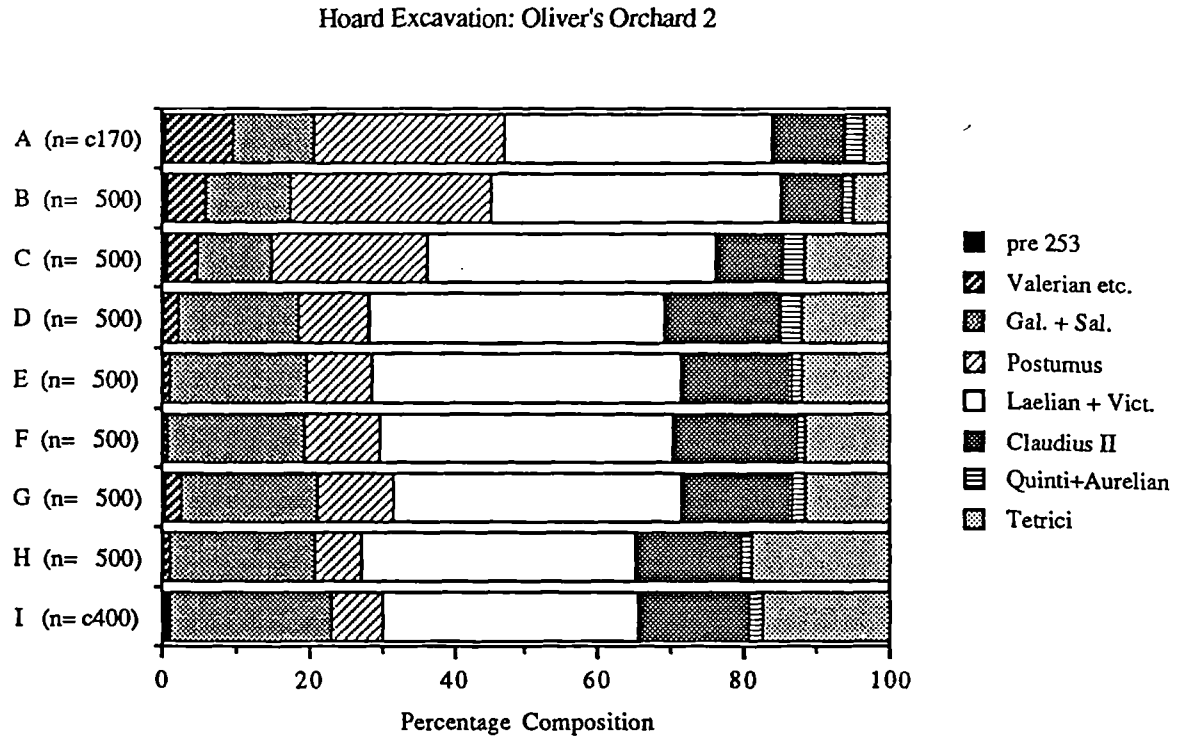

Fig. 21.03 The micro-excavation of the Oliver's Orchard hoard

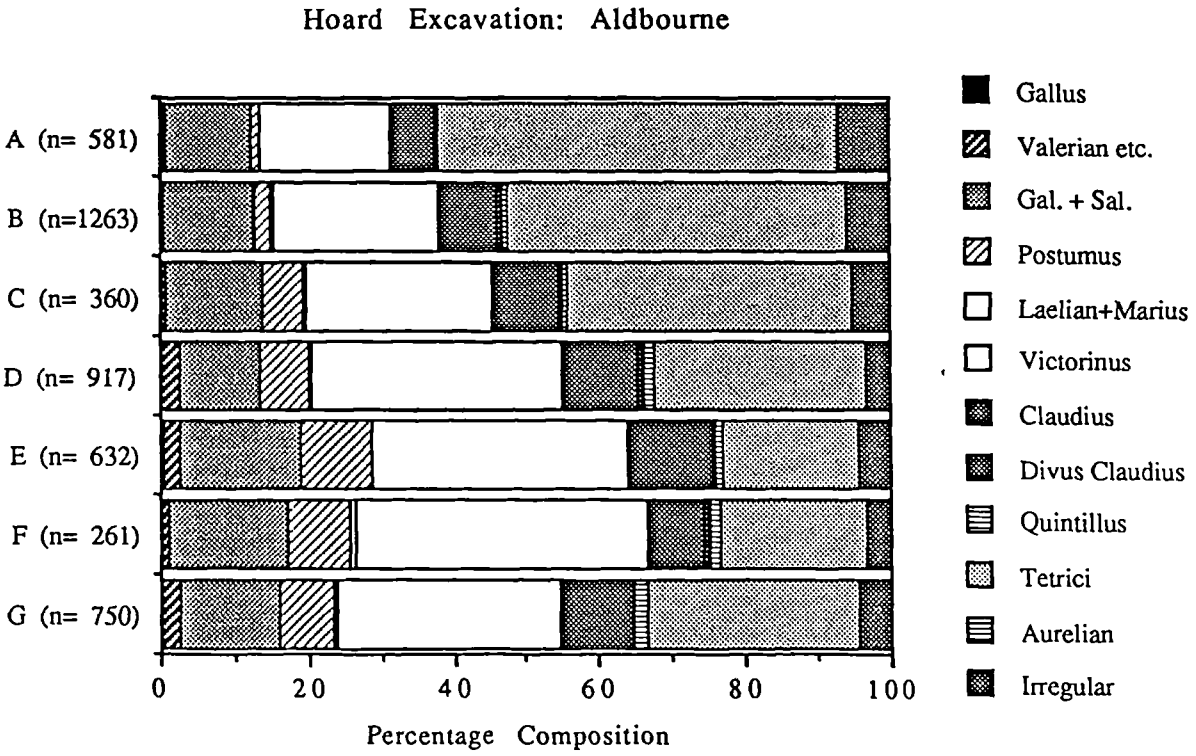

Fig. 21.04 The micro-excavation of the Aldbourne hoard

no way of knowing that the earlier coins of Valerian and his family were hoarded separately and only added at a later date. All that can be said is that this deposit is not a slow untouched accumulation of coins because the earliest coins are not at the bottom and the latest at the top.

The Aldbourne Hoard

The Aldbourne hoard of *antoniniani* and radiate copies contained over 4,700 coins; the latest official issues of which were Aurelianic and Tetrican coins of 273-4.

> "The distribution of Tetrican types is fairly consistent throughout the hoard and the latest types are present in all samples, so the accumulation of the hoard did not start before about 274. However, marked differences of composition can be observed between the uppermost and lowest parts of the hoard. The finest coins in the hoard (those struck before 260 and coins of Postumus struck before his debasement) are noticeably concentrated in the lower part of the hoard, but are virtually absent from the top."
>
> (Besly, 1984, 63)

The data (Besly 1984, 68) has been drawn up and is shown in fig. 21.04. Since the latest types occur at all levels, again we have a mixed up hoard. No steady accumulation of coins can be recognized. There is, however, some patterning: a higher proportion of the earlier and better coins were found at the bottom. This is exactly the reverse of the case in the Oliver's Orchard 2 hoard. Nonetheless this did not stop Besly interpreting the hoard as a 'savings hoard':

> "The differences of composition within the hoard suggest that Aldbourne may well be a savings hoard, rather than a single batch removed from circulation, in which case a date later than 274 may be suggested for its final deposit. The exact history of accumulation cannot be determined, owing to the arbitrary nature of the samples taken, but it seems that from about 274 the hoarder acquired several batches of coin; that which is represented by samples E and F being the best he could obtain at a time when the composition of the circulating currency was changing rapidly, and virtually all coins that were visibly silver were disappearing from circulation. The owner may have gathered his coins over a period, possibly of months, perhaps up to one or two years, but a date later than 276 for the final deposition of the hoard is possible though unlikely."
>
> (Besly 1984, 67)

This level of inference is well beyond what the hoard can legitimately be expected to provide. If anything, the changing composition of the hoard is reasonably gradual: no particular levels are very different from the last. The concept of acquiring 'batches' of coins, and putting them together certainly does not come from the evidence here.

The Tattershall Hoard

This hoard of about 5000 *antoniniani* and radiate copies contained coins up to Probus. The micro-excavated groups comprise the upper and lower half of the jar, and a scatter of

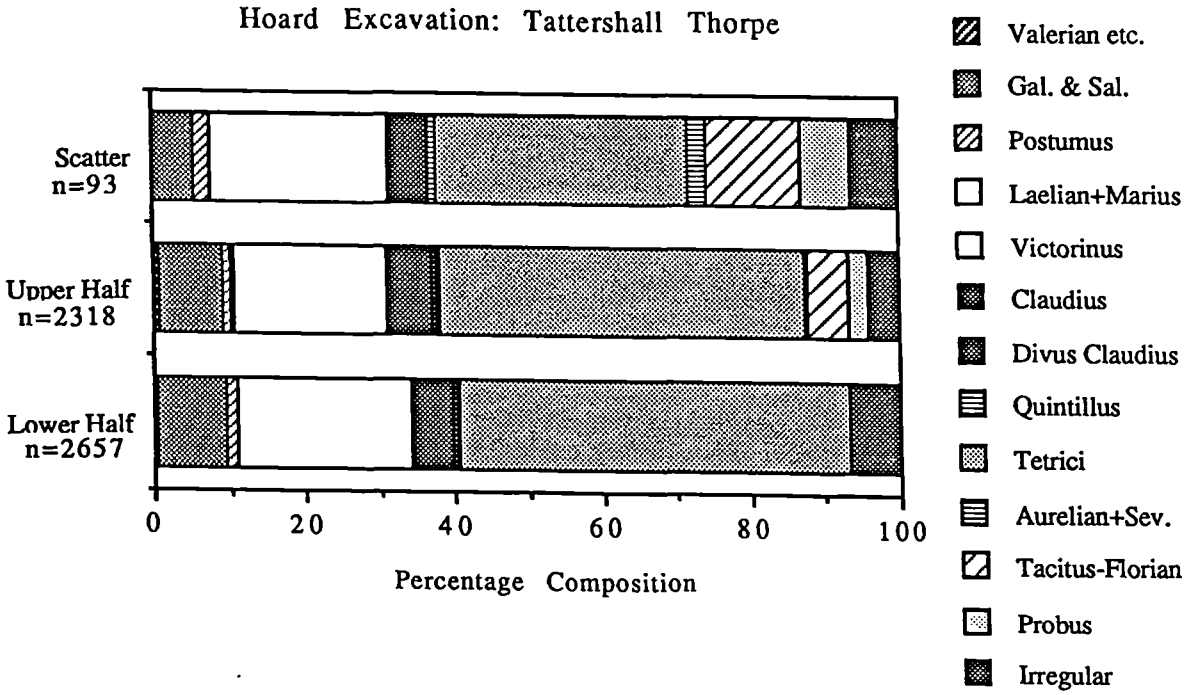

Fig. 21.05 The micro-excavation of the Tattershall hoard

93 coins which had been caught by the plough, and were not actually inside the hoard when excavated.

> "The overall composition of the upper and lower portions of the hoard are so similar in most respects, both in distribution of reigns and of types within reigns, that the hoard may be regarded as a single deposit, except in one important aspect. The 'reformed' coins of Aurelian, Tacitus, Florian and Probus were concentrated in the upper half of the hoard. It seems as though the 'reformed' coinages were gathered separately and added in a group to the top of the pot, an idea supported by the observation of some small clusters and rouleaux of post-reform coins in the upper portion of the hoard before cleaning. Segregation of pre and post-reform coins has been noticed before, in the Penard (Glamorgan) hoard, which closes with Carausius and is hinted at in the unpublished Kirmington (Lincs.) hoard, which included an apparently uncirculated batch of Lyon coins of Tacitus with many die-links."
> (Besly and Bland 1984, 106)

The data (Besly and Bland 1984, 106) has been drawn up in fig. 21.05. Unlike the Aldbourne hoard, the inference of a 'batch' of post-reform coins here is based on good solid evidence. However, this only tells us that the two denominations were hoarded and grouped separately. In the main body of the hoard we still have next to no vertical variation in the composition.

Conclusion

What does this analysis tell us? If we were looking for evidence of slowly accumulated savings hoards, then in our sample of five hoards we have failed. It could be argued that the hoarder may have tipped out his savings every now and then to count them. This is quite a reasonable suggestion. However, even if this were the case we would expect the differential selection factors between 'savings', 'emergency' and 'currency' hoards still to remain. Stirring up a hoard still would not alter the relative proportions of the different types of coin present. The next section moves on to search for these alleged differences.

2.14 Searching for emergency coin hoards

Hoards have been discovered from nearly all periods of the Roman occupation of Britain. Therefore, it would seem reasonable to suggest that there is such a thing as a 'background level' of hoard non-recovery. It would be unlikely that 'emergency hoards' were being deposited and lost due to warfare throughout all time periods, and that 'abandoned currency hoards' were being left all the time because the currency was so unstable. Because of this, periods of higher than normal non-recovery are sometimes equated with periods of warfare in Britain. One example of this is the Late Antonine period. Fig. 21.06 shows Robertson's chronological distribution of coin hoards in Britain. Undeniably there is a peak under Marcus Aurelius. To follow the theory, this peak should consist of some 'emergency' hoards as well as the normal background of 'savings

hoards'. This suggests that according to the 'emergency hoard - warfare' theory about 40% of the hoards should be 'currency hoards' and 60% should be emergency hoards.

According to the hoard typologies, the two types would reveal themselves by containing different proportions of various types of coin. The savings hoard would contain 'better' coins, since the hoarder had more leisure in which to choose and discard coins. This would generally mean that the hoard would have a more 'archaic' structure, since as a rule of thumb the earlier *denarii* contained a higher percentage of silver than the later ones. The emergency hoard, on the other hand, would have by comparison a more 'modern' structure, containing whatever was at hand at the time of impending disaster.

This can be tested by looking at the hoards themselves. The contents of hoards can be divided up into various chronological groups. This can then be run through a package such as Clustan (Wishart 1978), to see whether two groups of hoards form on numerical grounds. Since one of the principle reasons for variance is going to be the chronological distribution of the hoards within Marcus' reign, it would be as well to include in the analysis some earlier and later hoards, as a guide to the interpretation of the results.

The data comprises 55 *denarius* hoards from Trajan to Commodus. The hoard content was divided into the following groups:

1. Republican
2. Marc Antony
3. Augustus to Claudius
4. Nero
5. Civil War (Galba, Vitellius, Otho)
6. Vespasian & Titus
7. Domitian
8. Nerva
9. Trajan
10. Hadrian
11. Antoninus Pius
12. Marcus Aurelius
13. Commodus

These divisions are not perfect, but provide approximate guides. Ideally all the coins of Domitian would have been divided up into his various weight and alloy standards; and the Neronian coins would be divided up between the pre-reform and post-reform issues, but with many of the older coin reports this simply was not possible. But nonetheless, patterns should still appear. Of our 55 hoards, 37 are recorded well enough for this division above to be done precisely. With the other 18 it is possible that a few mis-attributions have been made. Mainly these will take the form of coins of Domitian not being divided into Domitian Caesar and Domitian Augustus, the former more properly being included under group 6. A similar problem arises with Marcus Aurelius, Faustina II and Commodus.

A nominal date has been provided for the deposition of each hoard. This is simply an average date given for the latest coin in the hoard. For example if the hoard ends with a coin of *c.* 176 to 180, the date has been given as 178. The data used has been provided in Appendix 2.11.

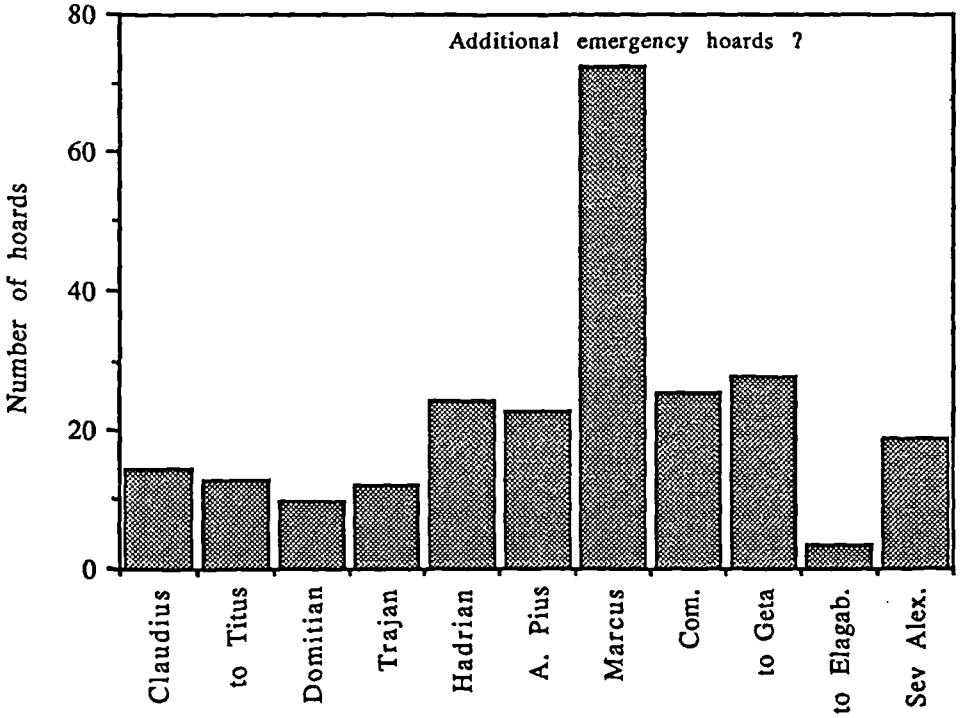

Fig. 21.06 Robertson's chronological distribution of British coin hoards

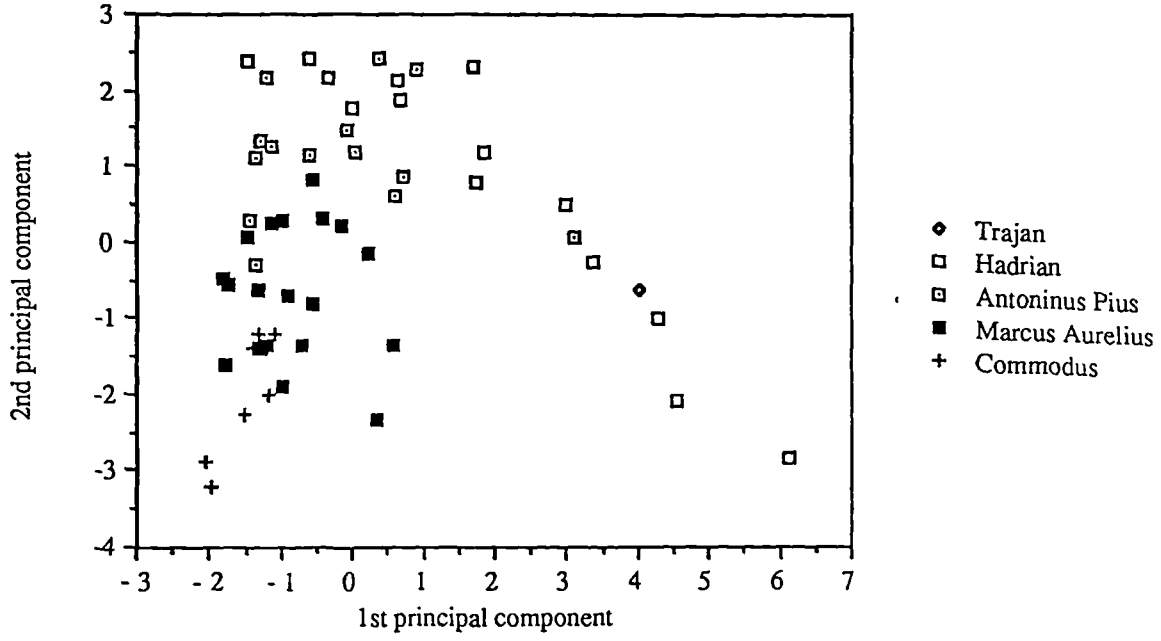

Fig. 21.07 The cluster analysis results

The model to be tested

If we have a division into emergency and savings hoards in the period of Marcus Aurelius then the picture we should get would be as follows: a sequence of hoards chronologically ordered representing the broad trend of savings hoards, with a blur between the boundary of hoards of Marcus Aurelius and Commodus. This blur would be the result of 'emergency hoards' which are suspected of having more 'modern' structures than contemporary savings hoards because of the savings hoard's predilection for earlier, better silver.

Analysis

The plot of the two principle components against each other is shown in fig. 21.07. These two variables account for 45% of the variance within the data. As can be seen, the hoards of Marcus Aurelius cluster quite well. There is a slight blur between the boundaries of hoards of Marcus Aurelius and Commodus, but then the same overlap exists between all the other chronological groups. A clear distinction between emergency hoards and savings hoards on numerical grounds as Reece sought (1987, 61) cannot be found here.

Interpretation

The increase in the number of hoards deposited ending with coins of Marcus Aurelius is undeniable, however, this analysis demonstrates that in this period where 'emergency' hoards are suggested, no ready distinction can be found between 'savings' and 'emergency' hoards. Therefore this does not appear to be a useful way of using and dividing our hoard evidence. The similarity and consistency between the hoards is far more striking than their diversity.

2.15 The equation of the hoard with the currency pool

The equation of the make-up of coin hoards with the contents of the circulation pool has been attempted and criticized by many people. Rogers made the link when examining the Corbridge and Liberchies hoards (Rogers 1975). On inspection of the *aurei* in the Liberchies hoard, he noted that the earlier coins were all slightly lighter in weight than the later coins because of wear. He even quantified this reduction in weight as being *c.* 0.024% p.a.. The Corbridge gold hoard, on the other hand, showed much less wear on the older coins. He concluded that the Liberchies hoard was that of a merchant, representing whatever was in circulation in AD166, the reason being that a savings hoard would rather have contained the better unworn pieces, whereas the Corbridge hoard was more likely to be a regular savings hoard.

One difficulty with this is the sheer unlikelihood of a large gold hoard being 'un tresor marchand'. The idea of any merchant's till consisting of large quantities of high value gold is hard to accept and would suggest a very large number of very high priced transactions. Surely the finite limits of justifiable inference which can be drawn from the data is that the gold from the Liberchies hoard in Belgium circulated (and was therefore worn) faster than the gold in Northern Britain. Even this inference, though, makes assumptions about the wear happening in the area of loss, ignoring the concept that gold can be highly mobile. The entire question of coin wear is returned to in Section 2.3. Secondly this particular example is all rather problematic since the Liberchies hoard was probably a Severan rather than an Antonine hoard (the later part not having been published yet, but having been commented upon in the trade). This explains the greater degree of wear on the Liberchies coins since they had been in circulation for around 60 additional years. nonetheless the form of Rogers' argument is what I am particularly interested in here.

Bruun on the other hand went to the other extreme; he stated quite correctly that "increasingly attempts to identify the composition of hoards with 'la circulation monetaire' necessitate some comments on the circumstances connected with hoarding and the validity of hoards as indicators of the mass of coins in circulation." (Bruun 1978, 114). He then went on to look at the occurrence on sites and in hoards of Constantine's billon 'Victoriae Laetae Princ Perp' coin of 311 and Licinius' coins marked with the value 12.5 (*denarii* ?). He discovered that in areas where the twelve and a half piece was found on sites it could nonetheless be absent from the hoards, with Constantine's coin being hoarded instead. This he took to demonstrate that hoards did not represent what was in circulation at the time. What this really demonstrates is not the blanket statement that 'hoards do not represent the coins that were in circulation', but that hoards of denomination X cannot tell us anything about the presence or absence of coins of denomination Y in circulation. It might still be possible for hoards of denomination X to faithfully reflect which of its own kindred were being handed around in the market place.

Other views of Coin Hoards and the Circulation Pool:

Many numismatists have expressed the view that if hoards are providing a consistent, regular picture, then they would feel able to correlate the pattern of coins of one denomination in hoards with what was in the circulation pool. For example:

> "Only when a number of hoards are of a similar pattern can we safely regard them as representative of the general circulating medium."
> (Grierson 1966, viii)

> "The proportions of coins of different reigns and types present in particular hoards are of course expressible as precise figures. These figures

> provide a very important guide to the relative commonness of these groups but they must not be taken as evidence of the presence of precisely those proportions among the coins in circulation unless this is borne out by a considerable body of homogeneous hoard evidence."
>
> (Archibald 1974, 236)

Crawford also saw this, though he qualified the equation of hoards with the circulation pool further by specifying that a large data base was needed, in order to remove various freaks and aberrations:

> "Equally important is the evidence provided by hoards for the study of coin circulation in its widest sense, not just the coinage in circulation at the moment when a hoard was deposited, but the whole pool of coinage which was available for circulation and which to a greater or lesser extent did pass from one person to another. Of course an isolated hoard may be a freak, the possession of a stray traveller, and inferences about circulation must only be based on a whole series of hoards."
>
> (Crawford 1983, 201)

If we wish to do this with Romano-British hoards then we need to establish whether homogeneity exists within the data, and gather a large enough corpus of hoards to iron out any variations. Both Robertson and Reece appear to be clearly of the view that the first criteria can be observed. Robertson stated that "...an analysis of well listed Romano-British hoards does show that a group of hoards of the same period had, as a rule, the same general composition..." (Robertson 1956, 270); and Reece in a quantitative study of a small group of hoards decided that there was such a thing as a 'normal' Severan silver hoard (Reece 1974a, 81).

In conclusion, if we can establish homogeneity within hoards of one denomination over a period of time, equating hoard content with the coinage in circulation seems reasonable. Indeed, recalling fig. 21.02, the vast majority of silver and gold 'in circulation' existed for most of its time in money-boxes and hoards. Analyses across denominations are much more dubious; and great care would therefore need to be taken where any coinage is going through a rapid transformation, such as the debasement of the *denarius* or *antoninianus* .

2.2 The Hoard Database

In this section the requirements of a hoard database are assessed (2.21). The hoard corpus is then introduced (2.22) with further comments about its structure and the codification of the database (2.23 & 2.24).

2.21 Database requirements

The quality of hoard publication has varied tremendously over the years, from the most rudimentary listing of 'a few emperors noted', to the most thorough treatment of works such as the Cunetio Treasure report (Besly & Bland, 1983). Yet even now, there is still no agreed way of publishing a hoard. Series such as the British Museum's 'Roman coin hoards in Britain' are inconsistent. Some hoards are published with the weights of the coin, whilst others are not. Some use Roman Imperial Coinage as the standard reference work, whilst others use the British Museum Catalogue. Somehow a database needs to systematize and contain this wide range of publication styles and levels of information.

The ideal form of a database depends upon its intended purpose and that is looking at large scale patterns in the circulation of coinage. So there is little point recording all hoards to the highest possible standard for the purposes of this work. Whilst a dozen hoards might be so recorded, the absence of such detailed information for hundreds of others would preclude any forms of large scale analysis being based on that level of information. If rarely published data, such as the weights of coins in hoards, are to be analysed (which they are in Section 2.3), then that information should be collected in a related but ancillary database. Similarly the full RIC identifications of coins have not been recorded. The reason is the same. Many hoards are recorded simply in the form of Emperor lists, and to maximize the number of hoards used in the forthcoming analyses it is to this lower common denominator that we must descend. In any case, full RIC identifications can be spurious. Ryan (1988) has shown that there is always a strong tendency for numismatists to identify a coin by the first similar type that occurs in the standard catalogue, rather than by its precise type, though the prefix 'As...' to the reference number in such cases is widely practised nowadays. This means that although published lists are a good guide to what is actually present, this does not mean that a second specialist would not arrive at a slightly different identification, despite the existence of detailed standard reference works.

2.22 The Database

The information is divided into two parts. First the corpus then the numeric data.

The Corpus (Appendix 2.21)

The rationale behind this database is the compilation of a large corpus of hoards from Britain such that a reasonable sample is achieved. The search has not been exhaustive for two reasons: first the older more obscure references which are most likely to have been missed are those which rarely contain any kind of useful information for these purposes anyway. Secondly such a corpus has long been in preparation by Professor A. Robertson, and it is not the purpose of this thesis to duplicate that work.

The breadth of the search for this corpus comprised:

Existing corpora:	Sutherland (1937)	Romano-British hoards in general
	Brickstock (1987)	4th c. hoards (particularly inc. Fel Temp issues)
	Sekulla (1980)	Hoards from Northern Britain
	Archer (1979)	4th c. precious metal hoards
	Shiel (1977)	Hoards including coins of Carausius & Allectus
Coin hoard series:	Coin Hoards from Roman Britain: Carson & Burnett (1979), Burnett (1981, 1984a, 1984b), Burnett & Bland (1986, 1987, 1989) and Bland (1982)	
	Coin Hoards: published by Royal Numismatic Society, London.	
Journals:	Numismatic Chronicle, British Numismatic Journal, Britannia and principle county journals.	
Listings:	Various hoards prior to publication by: P.J. Casey and R.J. Brickstock.	

All the hoards have been given an entry in a uniform format. The information in the corpus has been organized in the following way:

1. Location

   Place, County, National Grid Reference. Where the national grid reference is only given to four figures, this means that no specific information was forthcoming, so the reference can only be taken to be a general guide to the find-spot.

2. Date of discovery

3. Bibliographic references

   Primary references first, then further references as required. Not all of these references have been examined by the author. Some references when sought for appeared not to exist. These references have therefore been repeated without prejudice, though an indication that they are rather problematic has been incorporated.

4. A statement about the quality of the data
   Here it is stated whether RIC numbers exist in the original reference, or any other information such as coin weights, Elmer numbers or those from any other reference work. This is to enable anyone to assess the quality of information available about a hoard before following up the references.

5. Composition summary
   This is a breakdown by denomination of the number of coins present in the hoard. Indications may be given that the number is either approximate or a minimum figure. Where possible copies and genuine coins have been separated.

6. Terminus post quem:
   All hoards have been dated using a straightforward *terminus post quem* date or date range. The only exceptions to this are hoards terminating with coins before the invasion of Britain in AD 43 which have been given a nominal deposition date of AD 43, and the Icenian hoard series which have usually been assigned to the Boudiccan revolt of AD 60/61 (this is questioned later in section 4.1). The question of hoard dating is looked at in Section 2.6.

7. Reference number
   Each hoard is prefixed with a letter and a number. There are four letters used: B, S, A & C. In the cases of B, S & A this stands for the original corpora from which the information came (Brickstock, Sekulla and Archer). C series, which makes up the bulk of the database, are the further additions. The corpus is not a static body of hoard information just created for this thesis, rather it is continually being added to by new discoveries or older references which have subsequently come to light. Since the original ordering of the corpus was alphabetic, new insertions have been added into the sequence by the use of a letter. Eg. between C089 and C090 might be found C089n.

2.23 The Classification of the Data

The data appendices systematize all this information for hoards containing first to third century coins, published in their variety of formats, into a series of tables. The appendices are:

Appendix 2.22	*Denarii* in hoards
Appendix 2.23	*Antoniniani* in hoards
Appendix 2.24	'Bronze' coins in hoards

These tables are divided up by denominations. The appendices for *denarii* and *antoniniani* have the same format, though that for the *aes* is slightly different. With the *denarii* and *antoniniani* , those hoards which include fake coins have been given two entries. One for the genuine component of the hoard, and a second for the irregular coins. The irregular entries are denoted by the use of italics.

The first seven columns are summary data about the hoard:

1. The corpus reference number
2. The hoard name
3. The TPQ given for the hoard
4. The mean date from the above

4a. The type of coin present

This column (for the *antoniniani* table only) informs whether the data is for genuine coins, copies or both.

REAL Real coins only (as far as can be told).

COPY Copies only

R/C The total contents of the hoard without distinction between copies and genuine coins.

5. The status of the hoard

FULL All, or virtually all, the coins present within the hoard were identified.

PART Only a segment of the hoard was recovered and identified, therefore the data may be biased. Nonetheless the portion could still be representative.

NONE There was no reliable quantitative information about the hoard.

BIAS Only a selective portion of the hoard was described.

6. Count

OK The total number of coins in the hoard is more or less correct (whether or not all were identified). This information is provided for hoard size analysis. Therefore, if a hoard is recorded as having 100 coins in it, this is OK. If a hoard is said to have about 100 coins in it, this is OK; whereas if a hoard is said to contain over one hundred coins, this information is of no value. The idea of this is to get the order of size correct: 1000 vs 1005 coins makes little difference, 20 vs 25 coins does. The figure, therefore, is not necessarily exact.

No - Though there may be some information about a sample of the coins from this hoard, the original total number is not known.

7. Number

The total number of coins in the hoard. This is not the same as the total number of coins recorded in the tables, since the tables may only be recording PART of

the hoard. Even where the tables are recording the FULL information, the numbers may not be the same since illegible coins have been excluded from the tables.

If there is a discrepancy between a published summary and the catalogue in any respect, the catalogue has been taken as definitive.

All the further columns contain the breakdown of the number of coins of each emperor present. The emperors have been coded as follows:

Table 2.21: *Denarius* Codes

CODE	PRINCIPALS	Dates or relationship	Examples of infrequent coins	
A Den. 1	Republican	up to Augustus (excl. Den. 2)		
B Den. 2	Mark Antony	(40-31bc)		
C Den. 3	Augustus	(37bc-ad14)		
	Julia	Daughter of Augustus

The *denarii* and *antoniniani* have all been phased into groups. The function and use of these divisions are described below and in each individual section as required.

2.24 The problem of the Faustinas

The divisions used here are not strictly chronological. The reason for this can best be explained by reference to the coinage of the Faustinas. As has already been mentioned, while some coin reports are very detailed others simply comprise lists of emperors and members of their families present. Frequently an entry such as 'Faustina, 9 *denarii* ' is found. This is a problem. First there were two Faustinas, Faustina I (Senior) was the wife of Antoninus Pius, while Faustina II (Junior) was the wife of Marcus Aurelius. Not only this, but both Antoninus Pius and Marcus Aurelius minted coins for Faustina II; so here even an entry like 'Faustina II, 9 *denarii* ' would leave us in ignorance as to how many related to Antoninus Pius' reign and how many to Marcus Aurelius'. A division of the data into strict chronological slices, decided by imperial reigns is not going to work with this quality of data. There are two options. First to estimate how many might have been produced in each reign on the basis of other hoards with better details and then on this basis allocate the coins accordingly. Secondly, one could maintain the integrity of the data by lumping all the Faustinas into one group (that of Antoninus Pius), making the definition between the broad chronological groups slightly blurred. The second option has been preferred since it does not tamper with the original data.

The case of the Faustinas is by no means the only example of this kind of confusion. Frequently it is hard to distinguish in older reports between coins issued by individuals as Caesars or Emperors; or in the case of Domitian between him as a Caesar under Vespasian or Titus. Pragmatic decisions have to be made as to how to classify this poor quality of data. These decisions and the number of cases in which they have had to be made are given in table 2.23. To take one example: if no distinction is made between coins of Titus Caesar and Titus Augustus then the number of coins present is indicated in the column for Titus Augustus and the value 0 is also placed in the Titus Caesar column instead of the column being left blank. This acts as a missing data marker.

Table 2.23: The classification of poor quality data

No differentiation between	Place data under:	Place missing data marker under:	No. of Cases
Titus, Caesar or Augustus	Titus	Titus Caesar	13
Domitian, Caesar or Augustus	Domitian	Domitian Caesar	16
Marcus Aurelius, Caesar or Augustus	Marcus Aurelius	Marcus Aurelius Caesar	11
Faustina II, A.Pius or M. Aurelius	Faustina II (AP)	Faustina II (MA)	12
Faustina I or II	Faustina I	Faustina II (AP) & (MA)	5
Antoninus Pius, dead or alive	Antoninus Pius	Div. Pius	1
Lucilla, under M. Aurelius or Commodus	Lucilla (MA)	Lucilla (Comm.)	1
Commodus, Caesar or Augustus	Commodus	Commodus Caesar	4
Caracalla, Caesar or Augustus	Caracalla	Caracalla Caesar	1
Julia Domna, under Severus or Caracalla	Julia Domna (Sept.Sev.)	Julia Domna (Cara.)	6
Geta, Caesar or Augustus	Geta Caesar	Geta	2
Philip I & II	Philip I	Philip II	1
Valerian I & II (Caesar)	Valerian I	Valerian II Caesar	5
Gallienus, Salonina or Saloninus	Gallienus	Salonina (Sole reign)	9
		& Saloninus	6
Gallienus (Sole or Joint reign)	Gallienus (Sole Reign)	Gallienus (Joint reign)	17
Salonina (Sole or Joint reign)	Salonina (Sole Reign)	Salonina (Joint reign)	15
Claudius, dead or alive	Claudius II	Div. Claudius II	24
Tetricus I & II	Tetricus I	Tetricus II	18
Aurelius, pre or post reform	Aurelius pre reform	Aurelius post reform	33
Post Aurelian but pre Carausius, but with ... no other details	Probus	Tacitus, Florianus, Carus Carinus & Numerian	1
Diocletian, under Carausius or not	Diocletian	-	1
Maximianus, under Carausius or not	Maximianus	-	1

2.3 Coin Wear and the Velocity of Circulation of Coinage

In this section the contribution that coin wear can make to reconstructing the circulation pattern of coinage is addressed. The work of Rogers and Duncan-Jones is examined where it is always assumed that the rate of wear did not vary (2.33),. Learning the lessons from these analyses a different way of looking at coin wear is attempted allowing for the chronological variation in rates of wear (2.34-36). In the light of this some of Duncan-Jones' work on the circulation of sestertii *is reassessed (2.37).*

2.31 Introduction

The first analysis based on our database examines the wear on coins. This variable gives us direct access to information about the handling of coinage The more a coin is handled, moved or disturbed, the more abraded it will get and therefore the more worn.

> "Differential rates of wear can be distinguished between coins of the same denomination circulating at different periods and among the various denominations struck at any one time and circulating together: the later the period, the greater the wear; the higher the denomination the less the wear."
> (Archibald 1974, 237)

As Archibald makes clear, wear is variable. Low value coinage may circulate and get worn faster than higher value coins, also one type of coin may circulate and get worn at different rates at different times. Here the chronological and denominational differences are stressed, however there is no reason why similar patterning and changes might not be seen were the information to be divided up spatially as well. Coins may have circulated faster in the core of a circulation system, whilst moving slower in peripheral areas.

The more a coin is handled, the more one would expect it to become worn. This seems to be a reasonable working hypothesis. If it is the case, then it should be possible to use coin wear as an index of the degree of handling of coinage. The faster coin is being worn, the more use it must be getting in the system. This equation is very straight forward, almost simplistic. It is possible to raise some objections to it. For example, 'handling coinage' and 'money moving round the economy' are not necessarily the same thing. The contents of a hoard might by counted out once a month by its owner, thus abrading one coin against another. If for any reason the owner decided to count out his money once a week instead of once a month then we would observe a four-fold

increase in wear without any corresponding increase in the amount of work the coin was doing in the monetary system. The example is perhaps trivial, but other potential causes of wear on coin must be born in mind. Nonetheless, wear is one of the few direct measures of coin use we have access to, so it is worth proceeding on the working hypothesis referred to above.

2.32 How can wear be quantified ?

There are two principle ways, the description of the abrasion on a coin and its weight. Casey (1986,150-1) proposed the following system for describing abrasion:

> "The condition of the coin is that in which it was at the moment of loss; subsequent corrosion is ignored in trying to ascertain this state. Different workers have slightly different ways of indicating the condition. ... A range of conditions, all ultimately subjective, may be evident:
>
> UW - Unworn
> SW - Slightly worn
> W - Worn
> VW - Very Worn
> EW - Extremely worn
>
> Whilst of no absolute chronological value, the condition of wear should be recorded to give a general impression of the amount of use seen by the coins overall."

The benefit of this method is that it can differentiate between wear on coins and corrosion on coins. Whilst a coin might have lost weight by corrosive processes while it was in the ground, it might have been relatively unworn when it was lost. This can be told from the prominence of the features on the coin: does the head still stand proud or has it been worn almost level with the rest of the coin. However, the technique suffers principally because it is subjective, particularly on just such corroded specimens. Also it is rarely used in the publication of coin lists, whilst coin weight details are becoming more common (eg. the British Museum's Coin Hoards from Roman Britain series).

Coin weights are at least objective. However, like the description of wear, there are problems. Weight cannot differentiate between coins which are worn and coins which have become light by corrosion. Also, if conservation has been required on the coins, which weight should be used: the pre or post cleaning weight ? In all, weight has the two-fold advantage: different individuals can come up with consistent results and weights are now being published for a lot of coins.

Whilst we can weigh coins, this must not lead us into the temptation that we know their original weights when first issued. This can be estimated, and many authors have done so for most Roman coin issues, but the precise minting standard and the variation around that standard is not known. This must be taken on board in all analyses of coin weights.

2.33 Previous work on coin wear

Two authors have attempted to use coin weight as a means of understanding the way coin circulated: Rogers (1975) and Duncan-Jones (1987). Both had in common the analysis of the Corbridge and Liberchies (Belgium) *aureus* hoards, yet both looked at the data with very different goals in mind.

Rogers examined the weight of all the *aurei* of different dates in the two hoards. The pattern which emerged was that the Corbridge hoard contained heavier coins than the Liberchies hoard (the basic pattern of the data is shown in fig. 23.01 derived from Duncan-Jones' summary statistics). Working on the basis of a uniform rate of wear on the coins over time he fitted a straight line to the data implying a 0.0017 gms p.a. rate of weight loss from *aurei* in the Liberchies hoard. This he saw this as being an unselected hoard representing the general gold circulation pool at the time. Corbridge, however, did not correspond to such a nice even line, and it contained heavier coins. This he concluded was a function of selection.

Two critical points emerge from this. Uniformity across provinces is assumed: gold in northern Britain it is thought should show the same degree of wear as those in Belgium, if not selection must be the explanation rather than differential circulation rates. Secondly the straight line fitted to the data assumes an invariable rate of wear on gold from the Flavian period to the AD160s. But is this a fair assumption to make? The rate of circulation and wear on coins might well have varied during this period.

Duncan-Jones' analysis took this idea of regional variation on-board and examined a third gold hoard, this time from Portugal, along with the other two. However, he maintained the idea of a uniform rate of wear over time. His methodology is important and worth repeating, even though some of his uses of the data were decidedly suspect. As with Rogers, he uses the Liberchies hoard which is now known to be about sixty years later in date than the proportion of it published so far, but again it is the method and the assumptions made which I want to lay emphasis on here.

All three hoards were of the AD 160s. For each hoard the median weight of a series of selected Imperial issues was calculated (Table 2.31 and fig. 23.01). The short lived higher weight standard coins of Nero were quite reasonably excluded from the analysis. Regression analysis was then carried out fitting a line to these 'median weights' to see at what rate *aurei* were worn in each of the three hoards. Worryingly 'deviant data' was left out of this analysis for no clearly stated reason other than it did not fit in with the pattern expected. Also some median values derived from a small sample size which did not fit the pattern were excluded (Neronian coins in the Portuguese hoard), whilst

other small sample medians which did fit the general trend were included (coins of Marcus Aurelius in the Liberchies hoard). The trends therefore ended up almost fitting a straight line with very high correlations (R) of almost 1 (R = 0.88, 0.98 and 0.93). However, this masks the fact that much of the deviation in the data had already been removed by reducing subsets of the data down to their median values in the first place.

Despite some very suspect use of statistics the trends were clear to be seen. The *aurei* from Portugal seemed to be showing the greatest rate of wear over time, followed by Liberchies then Corbridge. This at least suggests that there is a regional factor to be considered in the rate at which coin circulated. Yet as with Rogers, a uniform rate of wear is assumed by the imposition of a straight line upon the data. If there was any chronological variation in the rate of circulation of coinage, then this type of analysis will not be able to reveal it.

Table 2.31: Median weights in 3 gold-hoards (From Duncan-Jones (1987) Tables I-III) Raw data represented in fig. 23.01 (including 'deviant cases')

		Corbridge (159/60)		Liberchies (166)		Portugal (168)	
'Date'	Emperor	Weight	Sample	Weight	Sample	Weight	Sample
66	Nero	7.155	(10)	7.02	(67)	(7.225)	(4)
74	Vespasian	7.19	(25)	7.06	(82)	7.05	(23)
108	Trajan	7.195	(48)	7.095	(66)	7.20	(28)

Duncan-Jones went on to analyse three silver hoards by the same method, again leaving out deviant data. The three hoards from Britain (Londonthorpe c.AD153), France (La Magura AD196) and Rumania (Viuz-Faverges c.AD 252) showed similar rates of wear. Following this he looked at *sestertii* from one hoard in the Garonne; however, here a very non linear relationship was found which led to an interpretation of a change in issue weight of the coin. This we will return to later.

2.34 The development of a new model

What then are the specifications we require of a new model of the rate of wear on coins?

1. It must not look at all the coins of different emperors together as they may have been issued to slightly different weight standards AND their differential metallic composition may cause one series to wear faster than another.

2. The method must take account of the possibility of a chronologically variable rate of circulation of coins.

3. If looking at more than one province it must account for the possibility of differential rates of circulation in different areas.

There are 15 *denarius* hoards from Britain published with good weight information. Most of them are from the British Museum's 'Coin Hoards from Roman Britain' series. The hoards are:

C 221	Scole	c. AD 61	-	Wervin, Cheshire	c. AD 157
C 103	Eriswell	c. AD 61	C 249	Waddington	c. AD 161
C 179	Mildenhall	c. AD 80	C 257	Westgate	c. AD 170
C 130	Howe	c. AD 87	C 001	Aldworth	c. AD 177
C 064	Cirencester	c. AD 94	C 010	Barway	c. AD 186
C 246	Verulamium	c. AD 117	C 120	Great Melton	c. AD 195
C 158	Londonthorpe	c. AD 155	C 004	Akenham	c. AD 221

The full information on these coins is contained in Appendix 2.31 where the Emperor, RIC number and weight for each is recorded (where known). The ideal would be to examine the decline in weight of each Emperor individually, alas the data is not sufficient to enable that to be done satisfactorily. So the following groups have been used:

GROUP 1	Republican	Den 1-2
GROUP 2	Claudius to Nero	Den 4-5
GROUP 3	Civil War	Den 6-9
GROUP 4	Vespasian	Den 10-11, 13 (Domitian Caesar)
GROUP 5	Titus	Den 12, 13 (Domitian Caesar)
GROUP 6	Domitian to Nerva	Den 14-15
GROUP 7	Trajan	Den 16-17
GROUP 8	Hadrian	Den 18-20
GROUP 9	Early Antonine	Den 21-23, 25
GROUP 10	Later Antonine	Den 24, 26-37
GROUP 11	Early Severan	Den 38-45
GROUP 12	Macrinus and Later	Den 46-54

Note 1: Because of the generally high quality of hoard reports in the British Museum volumes it has been possible to differentiate between Domitian Caesar (Den 13) coins under Vespasian and Titus, therefore the database has been enhanced to take account of this for this analysis.

Note 2: The early Julio-Claudian coins have been omitted from this analysis since their numbers in circulation after the Neronian reform of the silver are too small to enable any reliable statistics to be created from them.

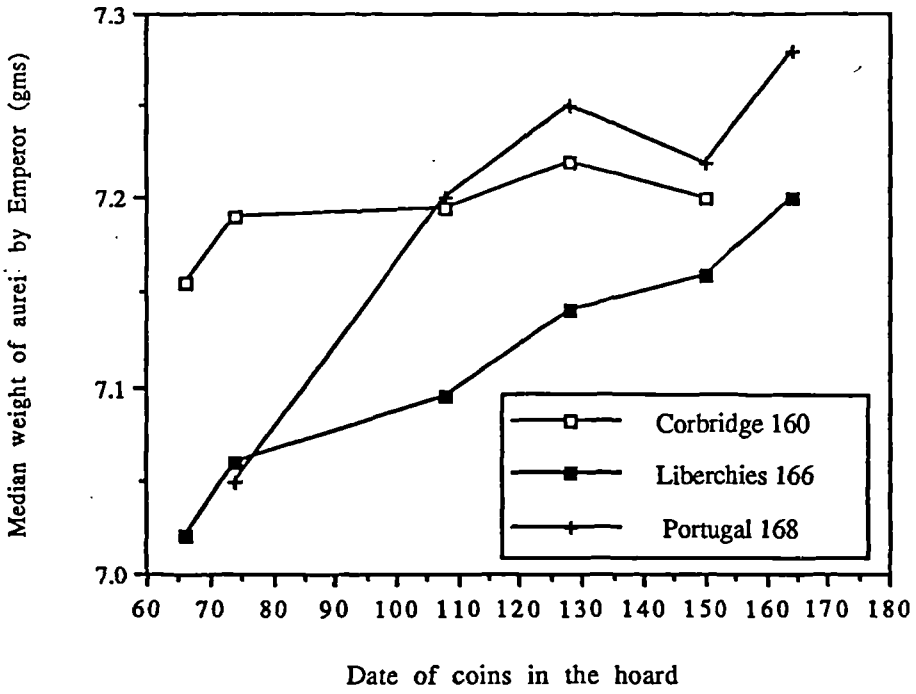

Fig. 23.01 Duncan-Jones study of three gold hoards: including the 'deviant' data points

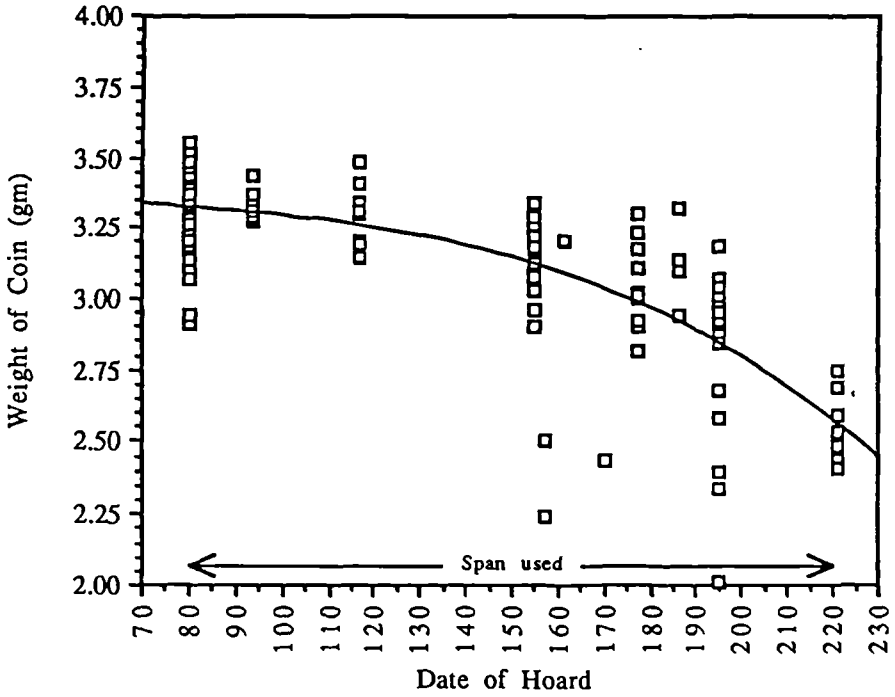

Fig. 23.02 The weight of Vespasian's *denarii* in hoards

$W = 3.4493 - 0.0028\,t + 0.00002762\,t^2 - 0.0000001489\,t^3 \quad R = 0.74$

2.35 An example: the *denarii* of Vespasian

Duncan-Jones and Rogers both examined all the Emperors within an individual hoard. Here let us look at it the other way. Let us follow the progressive weight loss of the coinage of one Emperor throughout the circulation life of the series. Fig. 23.02 shows just this for the coins of Vespasian. Each square represents an individual coin found in a hoard. Since each coin will have had an individual circulation life no reason is seen to compress this data into an average weight for each hoard. The full variation in the data should be allowed to show through. As one would expect, as time goes on the coins gradually get lighter and lighter. However, what is also apparent is that the rate of this decline does not appear to be uniform. It appears to accelerate. This pattern needs to be quantified. Rogers and Duncan Jones both fitted straight lines to such data, this would be entirely inappropriate here, since it is the observation that there is a change in the gradient that is interesting. Instead we can fit some simple polynomial curves to the data. In doing this all the data has been used, not just the medians from each hoard. This means that our degrees of correlation (R) will be much lower than Duncan Jones' values of nearly one, simply because the data has not already been smoothed as his selection of the medians did. What order of polynomial should be used? The higher the order, the more varied the shape of the curve fitted will be. However, a high order curve may not necessarily provide us with a useful description of the trends in the data, even though the mathematical correlation with the data will be better. This can be explained by reference to fig. 23.03.

In this case, though the trinomial (third order polynomial) passes very close to all the data points its relationship to the trend we are examining is minimal, and better represented by a simpler binomial (second order polynomial) or even a straight line. This problem, however, only occurs with some of the late series to be examined later, where there are only a few hoards containing data, in these cases a lower order curve has deliberately been used. Whichever, this curve only represents a crude guide to the patterning in the data, but it should be able to identify broad trends in it.

For Vespasian the following curve can be fitted:

Weight of coin = $W = 3.4493 - 0.0028\,t + 0.00002762\,t^2 - 0.0000001489\,t^3$ $(R = 0.74)$

This equation can tell us the normal weight of a *denarius* in a Romano-British coin hoard at date t. However, we are more interested in describing the rate of change of that weight. This is achieved by differentiating the equation above; differentiation of the equation is a way of calculating the slope of the curve:

Rate of change of weight = $dW/dt = - 0.0028 + 0.00005524\,t - 0.0000004467\,t^2$

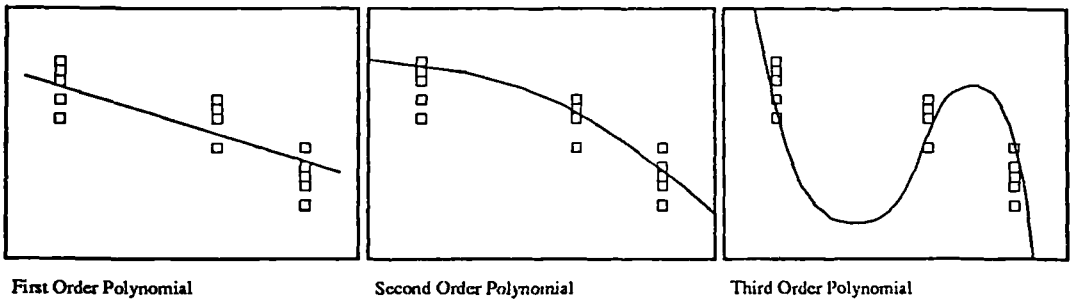

Fig. 23.03 Problems of fitting high order polynomial curves to hoard data

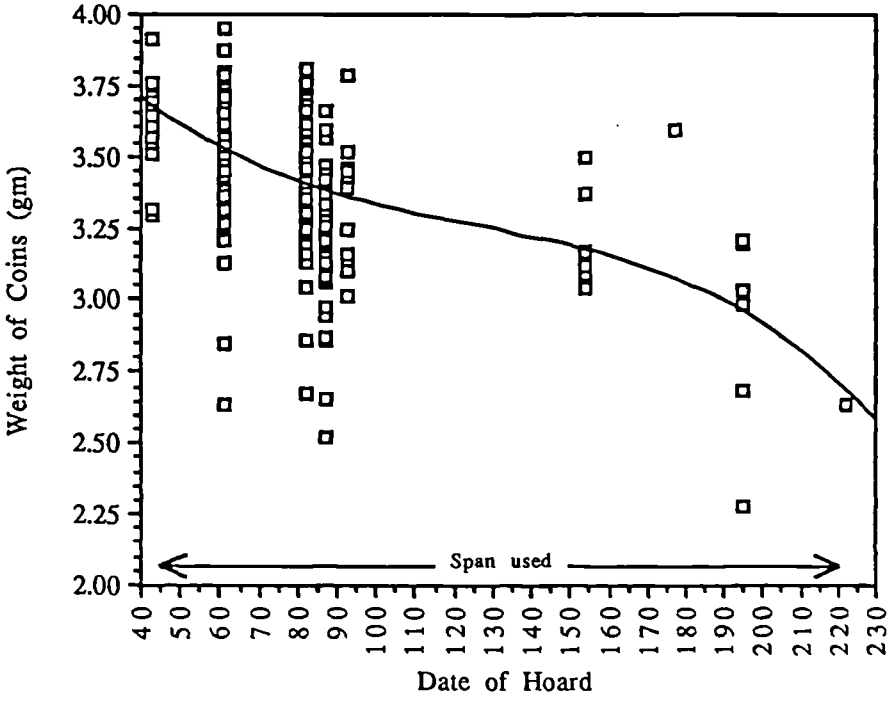

Fig. 23.04 The weight of Republican *denarii* in hoards
$W = 4.2904 - 0.0194\,t + 0.0001330\,t^2 - 0.0000003517\,t^3$ $R = 0.52$

2.36 Rates of Wear of all *denarii* in Britain

The Vespasianic coins have shown that there is a chronological variation in the rate of coin wear. This pattern should also be reflected in the other coin series to which our attention now turns. The same procedure has been carried out with all the remaining groups. The curves are shown in figs. 23.04-23.10.

Table 2.32: Curves derived from the weights of *denarii* in hoards of different date:

Republican:	W=	4.2904	-0.0194 t	+0.0001330 t^2	-0.0000003517 t^3	R = 0.52
Claudio-Neronian:	W=	5.549	-0.0501 t	+0.0003501 t^2	-0.0000008153 t^3	R = 0.84
Civil War Issues:	W=	4.6009	-0.0288 t	+0.0002142 t^2	-0.0000005617 t^3	R = 0.70
Vespasian:	W=	3.4493	-0.0028 t	+0.00002762 t^2	-0.0000001489 t^3	R = 0.74
Titus to Nerva:	W=	4.9956	-0.0345 t	+0.0002388 t^2	-0.0000005788 t^3	R = 0.45
Trajan:	W=	2.0784	+0.0148 t	-0.00004897 t^2		R = 0.17
Hadrian:	W=	3.8765	-0.0043 t			R = 0.25
Antoninus Pius:	W=	-1.373	+0.0556 t	-0.0001676 t^2		R = 0.38
Later Antonine:	W=	-3.4629	+0.0767 t	-0.0002231 t^2		R = 0.38

Table 2.33: Differentiations of the equations in Table 2.32, representing the rate of wear on coins:

					Valid for:
Republican:	dW/dt=	- 0.0194	+ 0.0002660 t	- 0.0000010551 t^2	AD 45-220
Claudio-Neronian:	dW/dt=	- 0.0501	+ 0.0007002 t	- 0.0000024459 t^2	AD 60-195
Civil War Issues:	dW/dt=	- 0.0288	+ 0.0004284 t	- 0.0000016851 t^2	AD 80-195
Vespasian:	dW/dt=	- 0.0028	+ 0.00005524 t	- 0.0000004467 t^2	AD 80-220
Titus & Nerva:	dW/dt=	- 0.0345	+ 0.0004776 t	- 0.0000017364 t^2	AD 80-195
Trajan:	dW/dt=	+ 0.0148	- 0.00009794 t		AD 155-195
Hadrian:	dW/dt=	- 0.0043			AD 155-195
Antoninus Pius:	dW/dt=	+ 0.0556	- 0.0003352 t		AD 155-220
Later Antonine:	dW/dt=	+ 0.0767	- 0.0004462 t		AD 175-220

How well do the results of all these coin series compare? Do all the series experience fast rates of wear at the same time? Is there any consistency in the patterning? What would be helpful is some kind of composite picture representing all these curves. The reason why we studied the *denarii* in Emperor groups was so that we made no assumptions about all the *denarii* being issued at the same standard throughout the Principate, however now we have got 'rate of wear' equations from our graphs it is possible to amalgamate the information since these equations place no reliance upon any supposed minting standard. The only remaining provision being that the

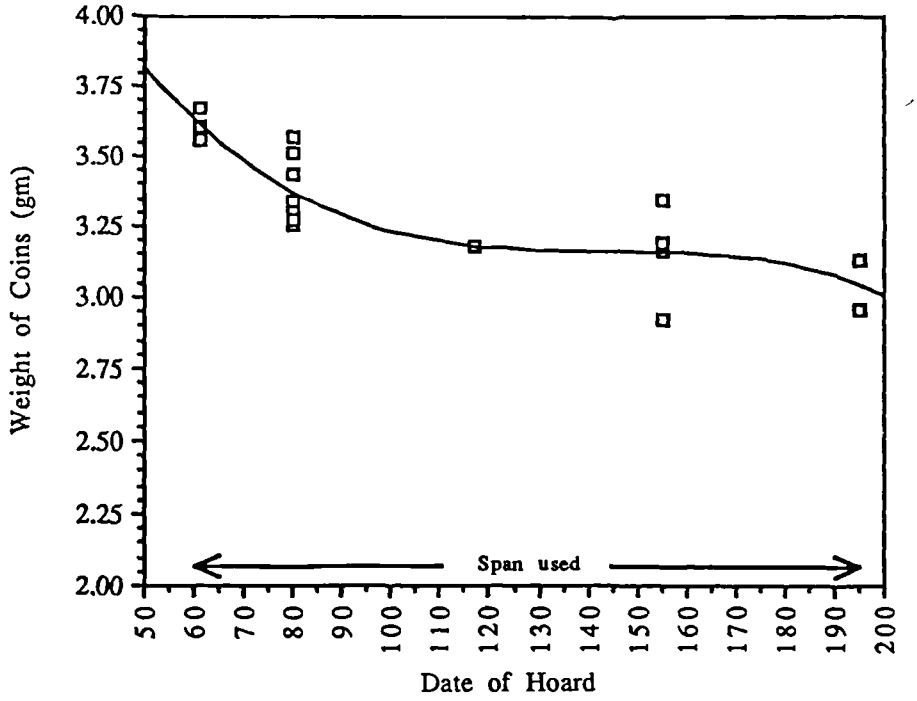

Fig. 23.05: The weight of Claudio-Neronian *denarii* in hoards
$W = 5.549 - 0.0501\,t + 0.0003501\,t^2 - 0.0000008153\,t^3$ $R = 0.84$

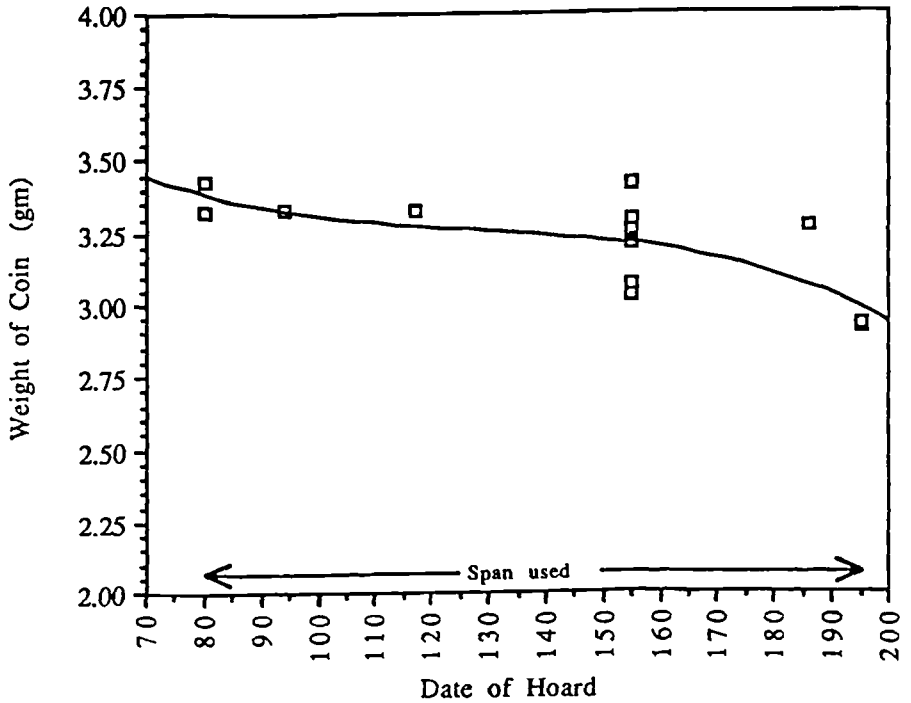

Fig. 23.06: The weight of Civil War *denarii* in hoards
$W = 4.6009 - 0.0288\,t + 0.0002142\,t^2 - 0.0000005617\,t^3$ $R = 0.70$

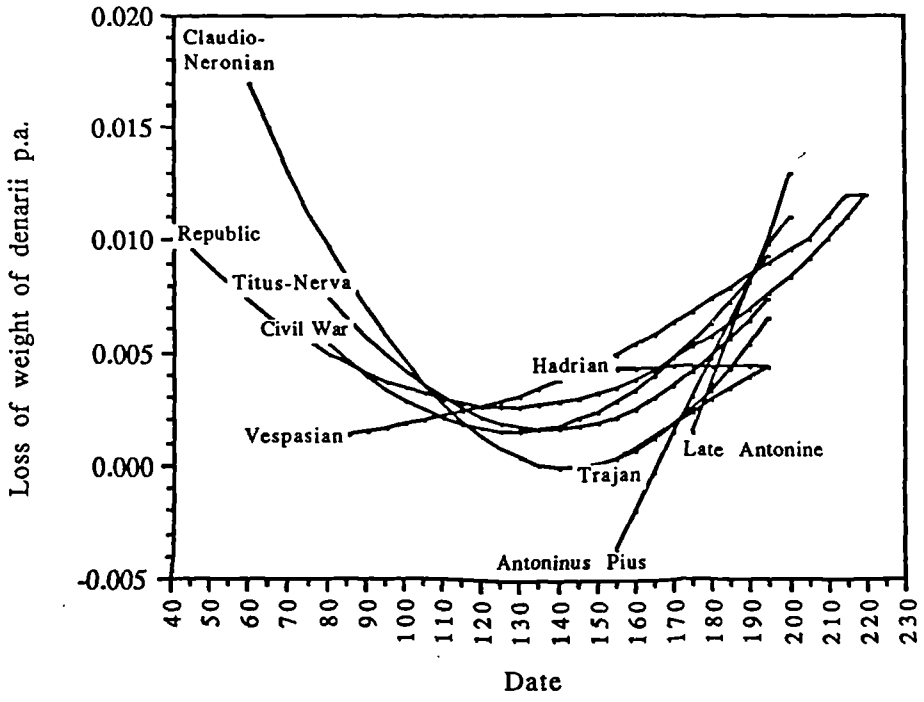

Fig. 23.11: The rate of wear of *denarii* amongst the nine individual coin groups

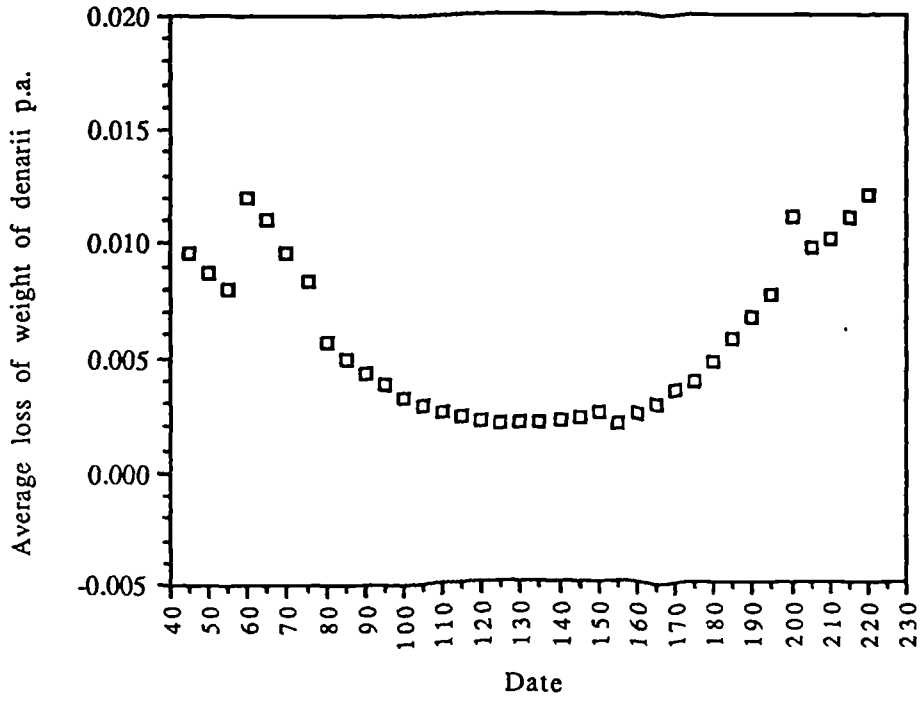

Fig. 23.12: The rate of wear of *denarii* in Britain, averaged from all the coin groups

composition of the *denarius* is known to have changed over time, and therefore the durability of the metal might have altered with it.

Fig. 23.11 shows the rate of wear curves for the nine series. From this graph it is clear that the general trend is very systematic, with the rate of wear declining up until the early second century AD, and then starting to rise again. The nine curves have been averaged in fig. 23.12. If the graph is taken at face value then the implication is that instead of a steadily developing monetary economy in Britain, with *denarii* circulating faster and faster, what we have is the reverse to start with. *Denarii* start off by being handled and worn a great deal (c. 0.010 gms pa), although this rate declines to a quarter (0.0025 gms pa) by the early-mid second century, only then to start to rise again. This pattern is not what one might have expected, however it is derived from concrete data rather than a complicated model. Nonetheless, corroboration from another method of calculating the rate of circulation of coinage would be welcome.

It must be noted that in fitting polynomials to the data, just as in fitting straight lines, a certain degree of information is suppressed. The result will end up as a simple curve rather than a variable squiggle by definition of the method. The curve in fig. 23.12 therefore only represents the general trend, it can have no claim to be a precise detailed representation of the changing wear rates of *denarii* in Britain.

2.37 The circulation of *sestertii*

As mentioned above, Duncan-Jones also did some work on the *sestertii* in the Garonne hoard. Though in France rather than Britain, a re-interpretation of his results has a bearing upon the results of the *denarius* survey above.

Duncan-Jones found the fitting of a straight line to these weights more difficult than in his previous analyses. This he explained away by conceiving a change in the weight standard of *sestertii* . This meant it was easy to explain away the low weight of the later *sestertii* because they were seen to have been minted to a lower weight standard. However, instead of looking for different minting standards, how would different rates of wear affect the pattern? Fig. 23.13 shows models for this kind of graph, where different issues of different dates are shown from a single hoard. The steeper the gradient, the faster the rate of wear must have been (fig. 23.13a). However, the gradient would only be a straight line had the coins circulated throughout their life at a uniform rate. Otherwise variation in the line would be expected (fig. 23.13b). Using this very simple model how could we reinterpret the weight of *sestertii* in the Garonne hoard (Table 2.34 and fig. 23.14)? What we have is a uniform rate of circulation from the mid 70s to AD 110-120. At this point the rate of wear in *sestertii* falls off. There are three possible interpretations:

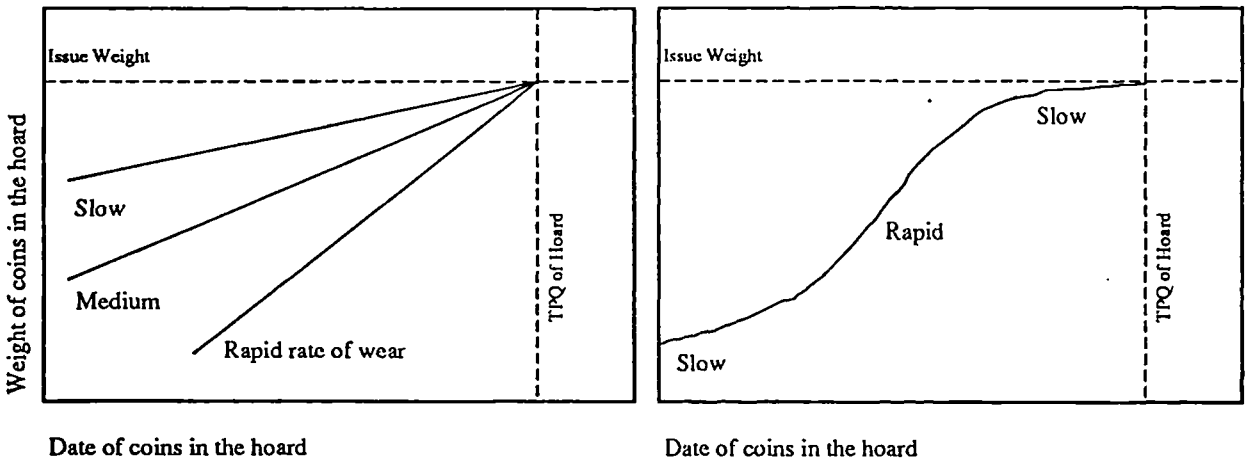

Fig. 23.13
Differential rates of wear and its effect on the weight of coins from a single hoard

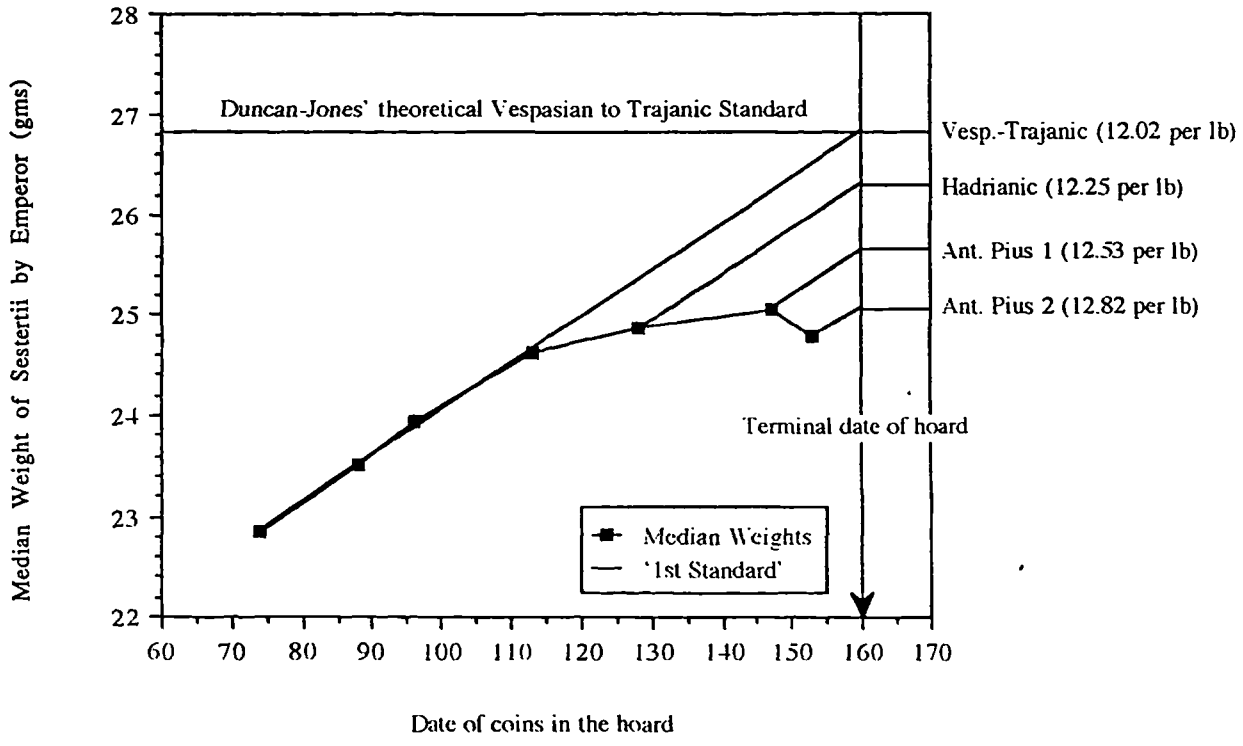

Fig. 23.14: The weight of *sestertii* in the Garonne hoard

1. In the Antonine period the rate of wear on *denarii* gradually increased, at the same time the rate of wear on *sestertii* can be interpreted as decreasing. Perhaps this reflects the *denarius* being handled more than *sestertii* as the *denarius* slowly became the more useful coin; in the same way that *sestertii* gradually took over from *dupondii* , *asses* and the other smaller bronze coins.

2. Perhaps the change in the rate of wear has nothing to do with contemporary changes in the handling of *denarii* . It may be related to the large numbers of *sestertii* now in circulation. If there were more *sestertii* in circulation (and coins of Hadrian and Antoninus Pius are by no means rare) perhaps on average each coin would have been handled less, therefore the rate of wear might have been reduced (assuming the average number of transactions remained the same).

3. Or perhaps the minting standard of *sestertii* did change and was reduced by Hadrian and then twice by Antoninus Pius.

If any, the author prefers the second interpretation, but a far wider range of *sestertius* hoards would have to be examined first, and the problem of estimating intended minting standards would have to be addressed.

Table 2.34: Median weights of Sestertii in the Garonne hoard
(From Duncan-Jones (1987) Tables IX-XI)
Data represented in fig. 23.14
The 'No. of *sestertii* struck per pound' is derived from the intersects on fig. 23.14

Emperor	Dates	Median Weight (gms)	Interpreted No. of Sestertii struck per pound
Vespasian	69-79	22.85	12.02
Domitian	85-91	23.52	12.00
Nerva	96-97	23.95	12.00
Trajan	112-114	24.64	12.01
Hadrian	128-129	24.865	12.25
A. Pius (1)	145-148	25.08	12.53
A. Pius (2)	149-156	24.785	12.82

2.38 Conclusions

It is likely that precious metal coinage was extremely mobile. Therefore it would be prudent to ask whether the weight of *denarii* in Britain is actually telling us anything about Britain *per se* , or is it possible that the wear on them is a far more general indicator of what is happening in the empire as a whole? Did the wear being measured actually take place in Britain, or did it take place in the whole of the Empire, with the coin simply terminating its European tour by being fossilized in a hoard in Britain ? There is no intrinsic evidence that will tell us this. The fact that changes in the rate of wear of *denarii* in Britain and *sestertii* in Gaul takes place at the same time suggests

that changes are taking place on a multi-provincial scale. Also Duncan-Jones' analysis of the Londonthorpe, La Magura and Viuz-Faverges *denarii* hoards of Britain, Rumania and France suggested similar rates of wear in each; though as noted there were problems with his methodology.

For the moment the conclusions drawn from this section are:

1. From the conquest to the early second century *denarii* slow down in their rate of circulation in Britain.

2. From the early second century to the early third century *denarii* may slowly increase in their rate of use in Britain. No information beyond this date is possible from this analysis.

3. This pattern may reflect a wider picture than Britain alone, depending upon how mobile silver was between provinces.

4. *Sestertii* in Western Gaul show a decrease in use in the early to mid second century, which *may* relate to an increase in the numbers of *sestertii* in circulation at the time. However, this conclusion is not particularly secure.

5. Corroboration from a different form of analysis would be welcome.

2.4 Uniformity and Variability in Hoards

A broad pattern of similarity is found amongst British denarius hoards of the same date (2.41 & 2.42), however, this is not to say that their composition is entirely uniform. Reasons for variation in hoard structure are discussed (2.43), and contingency tables are used to see if this variability is consistent over time (2.44). It is not, and reasons are sought for this (2.45 & 2.46).

2.41 The 'normal' hoard

If we are to study *denarius* hoards in Britain then we need some kind of bench-mark against which to say 'this hoard is typical for a hoard of that date' or 'this hoard is exceptional in its construction'. Furthermore, if we to are equate *denarius* hoards with slices through the circulation pool, frozen in the form of a 'money-chest' which for what ever reason were not recovered, then an idea of the changing structure of coin hoards would inform us about the changing structure of the circulation pool as a whole. However, as has been noted above, this can only be justified if there is such a thing as the 'normal hoard' with all hoards showing a reasonably consistent pattern.

So are hoards predictable in their composition ?. Reece's analysis of seven Severan hoards in Britain (Reece 1974a) quite clearly showed that they could be. All had a very similar composition within the limits of the analysis. So similar that 14 years later he reflected that:

> "the important point is that in the hoards discussed in this paper there are no eccentric hoards, they are all alike. The really eccentric hoard, such as that from Falkirk, stands out very prominently."
>
> (Reece 1988, 101)

From Reece's work we can move forward beyond an analysis of seven hoards of more or less one date, to a study based on the entire span of the *denarius*' duration in Britain and with all the hoards drawn from our database for which reasonable data exists. The specifications for the level of information we require is that we can describe the hoard in terms of the Emperor groups noted above (Section 2.2). Further there must be enough information in the publication to tell us that the details represent all the coins that were found, or virtually all; otherwise selective fractions of the hoard may have been spirited away distorting the data. Imitation *denarii* have to be excluded from the information and the sample size has to be above some minimum figure which has arbitrarily been set here at five coins.

Total number of hoards in data-base:	784
Hoards containing genuine *denarii* :	212
Hoards where the number of coins are known:	187
Hoards where there are sufficient details:	148
Hoards where there are more than five *denarii* :	125

Our aim is to obtain an overall picture of the changing composition of hoards. Cumulative frequency graphs have been used plotting all the coins issued up to a certain emperor. This has been done in preference to plotting the proportion of each emperor in hoards individually since it makes better use of the data where the quality of information about a hoard is imperfect. For example: frequently, in the Antonine period, it is impossible to tell how many coins relate to the reign of Antoninus Pius and Marcus Aurelius. The reason for this is that coins may be published simply as 'Faustina' without any clue as to whether they belong to Faustina I (Antoninus Pius) or Faustina II, let alone whether if of Faustina II they were issued under Antoninus Pius or Marcus Aurelius. A similar problem occurs with coins of Marcus Aurelius as Caesar or Augustus and Antoninus Pius whether in his primacy or posthumously. Were the plots to be done individually then data from such hoards could be used in neither an Antonine curve, nor one for Marcus Aurelius as their values would be suspect. However, if the information is presented cumulatively, though we might not be able to use the information for a curve of coins up to Pius' death, we can at least use it for the next graph of coins up to the end of Marcus Aurelius for which the total will be correct, whatever the actual ratio of Antoninus Pius to Marcus Aurelius coins.

Cumulative frequency graphs were drawn showing the proportion of coins up to a certain series occurring in hoards at different dates. This was done for each coin series. Examples are shown in figs. 24.01-04. The data are given in Appendix 2.41.

As can be seen, there is a reasonable degree of consistency in the data, the curve for coins up to Trajan (fig. 24.02) showing the best results. If we examine this one closely, up until Trajan's reign coins of his and earlier issues represent 100% of the *denarii* in all the hoards. Only after this when new issues arrive of later emperors does this proportion drop until the mid third century when virtually all Trajanic and earlier *denarii* have disappeared from the circulation system. The curves for Vespasian (fig. 24.01) and Marcus Aurelius (fig. 24.03) show a similar picture. In the case of coins up to Elagabulus (fig. 24.04) the pattern is more dispersed, though one can imagine that by AD 280 they probably represent about 40% of the coins in circulation; though by this stage one must remember that there were probably hardly any *denarii* left in circulation at all, and the data comes from only a small sample recovered in large *antoninianus* hoards. The degree of scatter in the illustration probably reflects both this sample size effect and the variable residual nature of those *denarii* left in circulation at that date.

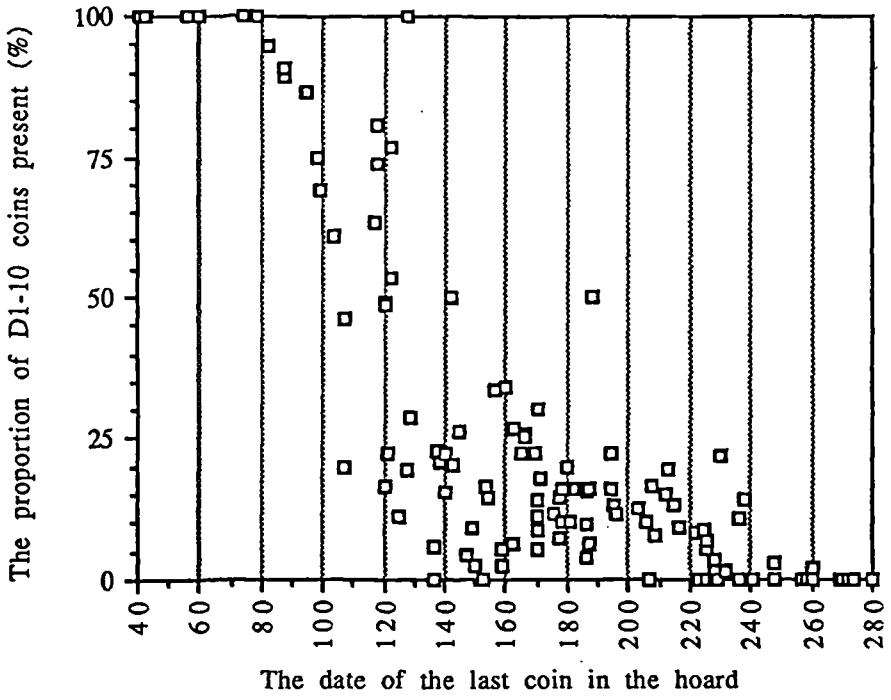

Fig. 24.01 The proportion of *denarii* up to and including Vespasian (D 10) in hoards

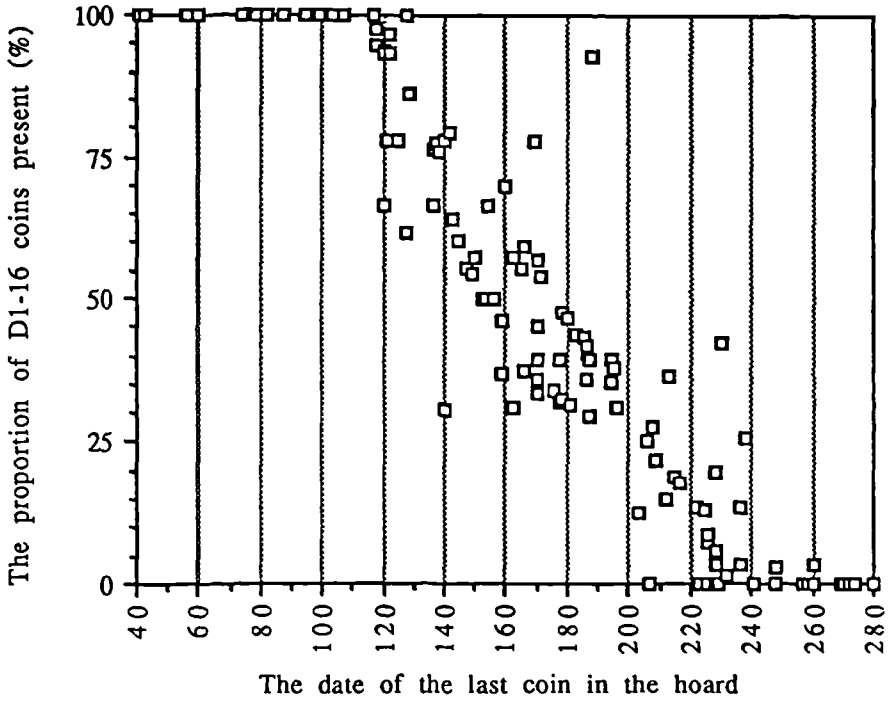

Fig. 24.02 The proportion of *denarii* up to and including Trajan (D 16) in hoards

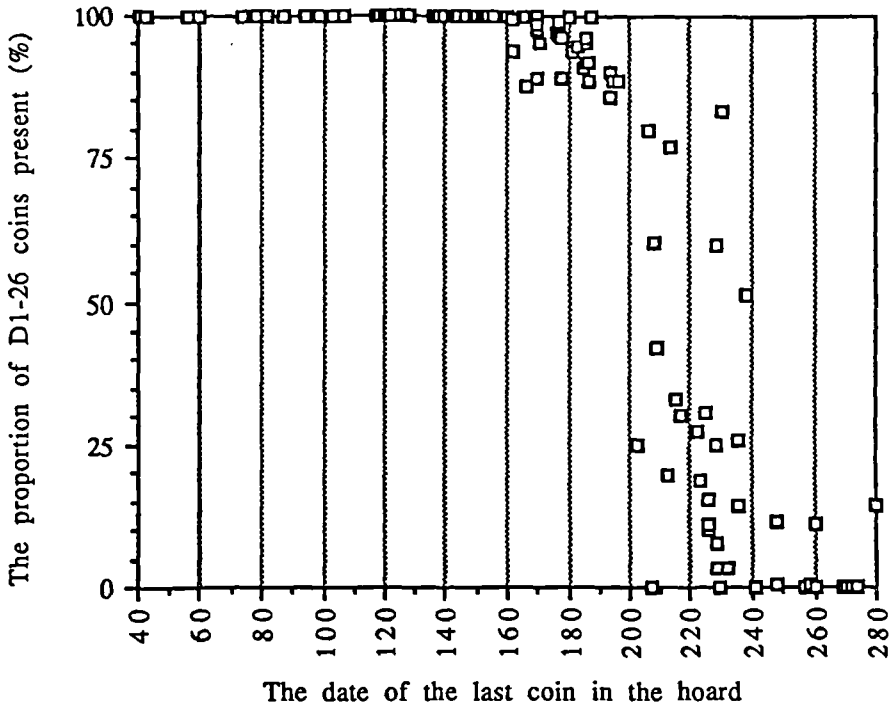

Fig. 24.03 The proportion of *denarii* up to and including M. Aurelius (D 25) in hoards

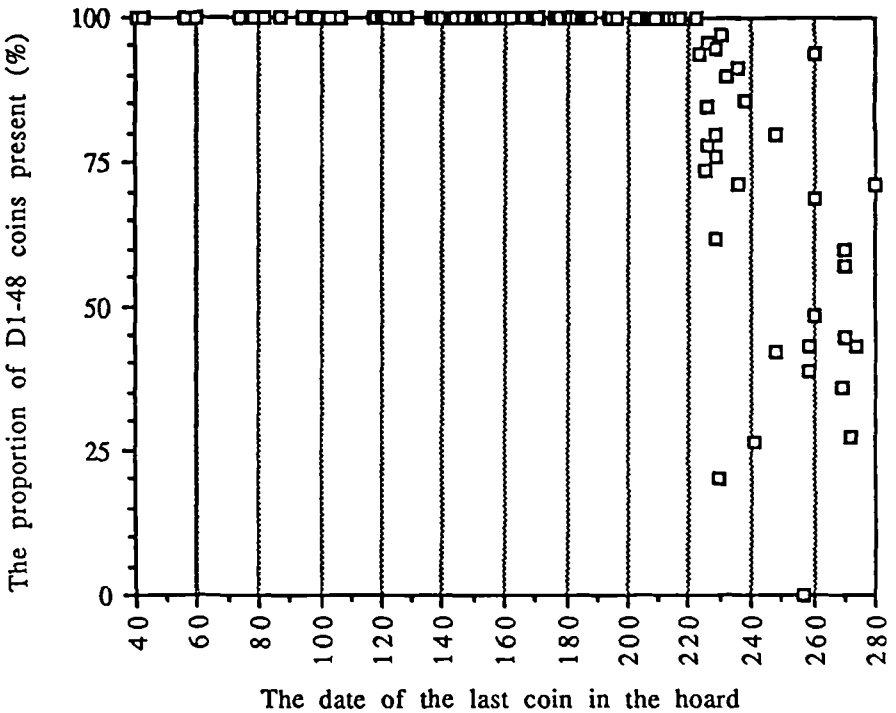

Fig. 24.04 The proportion of *denarii* up to and including Elagabulus (D 48) in hoards

What is clear is that there are broad general trends in the composition of *denarius* hoards. Reece's comments above for Severan hoards stand true just as much for all *denarii* hoards in Britain.

2.42 The creation of a bench-mark

From these curves we can create a bench-mark of 'the standard composition of *denarius* hoards in Britain'. This is intended to act as a useful yard-stick against which to measure individual hoards.

First, some kind of line needs to be fitted to the cumulative composition curves. The idea of fitting a simple mathematical curve to them would be inappropriate. There is absolutely no reason why any of the graphs illustrated should conform to a simple mathematical curve. Occasions such as the sudden input or withdrawal of a coin series in circulation would cause a step in the line which a fitted curve would in all probability smooth out. Instead, various interpolation techniques have been used and curves have been fitted to short sections of each graph. The final results are shown in fig. 24.05. The data for this is given in Appendix 2.42.

This illustration will now serve as our bench-mark representing 'normal hoard composition'. Comparison of the well defined lines to the spread of data shown in the proceeding illustrations should warn us that there is still much variation in the data, and the bench-mark only represents a guide to the average composition. The study of this variation we return to in section 2.43. But for the moment let us assess what this illustration tells us in its own right about the nature of the mixed circulation pool.

Fig. 24.06 shows us the same information as fig. 24.05, except that here it has been separated out into the individual coin groups. While looking at these one must remember that they do not represent *how many* coins of that series were in circulation at any one time, but rather the *proportion* which were. The difference is very important as they are not the same thing at all. For example, the proportion of the number of *denarii* of Groups B and F (Mark Antony and Vespasian) rise markedly around AD 120-140. This probably has nothing to do with more coins of these issues coming into Britain. In fact both rises relate to the sharp withdrawal of earlier Republican *denarii* from circulation at around this time. The difference between graphs of the proportional make up of the currency pool and the actual money supply is explored much further in Section 3.4, but for the moment let us remain with the hoards.

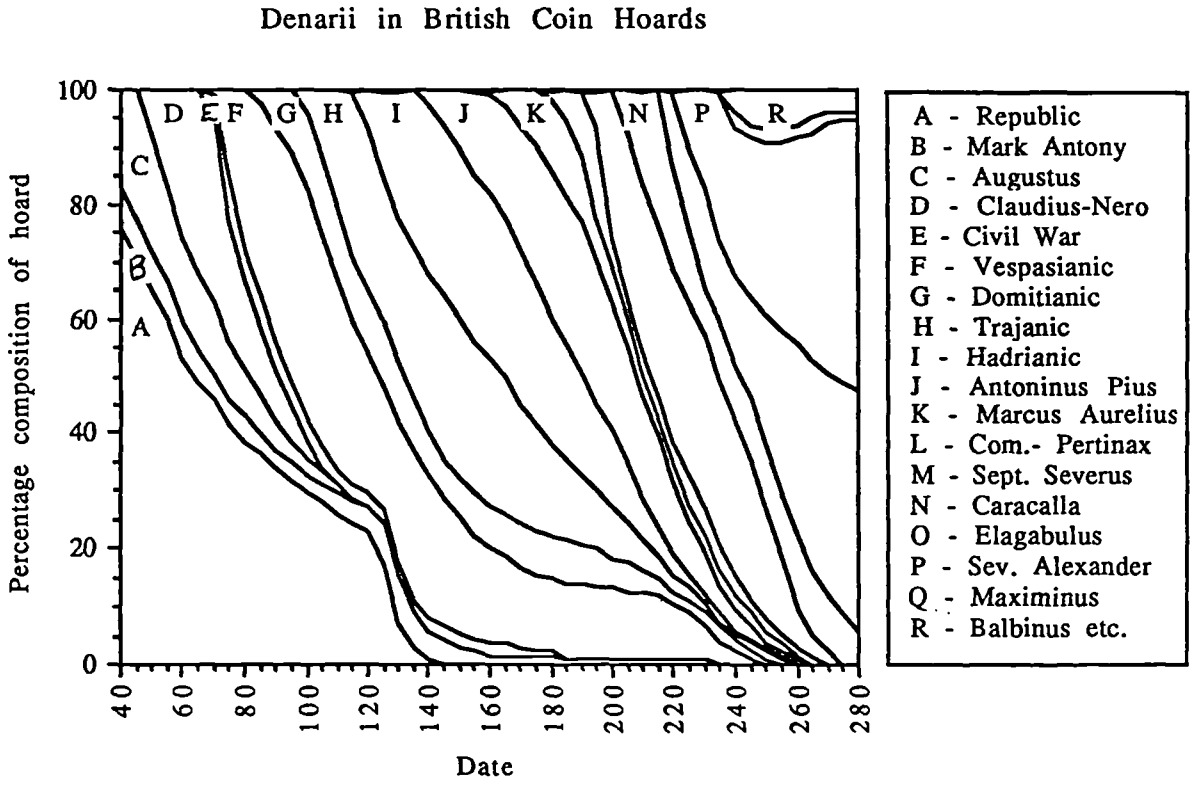

Fig. 24.05 The proportion of *denarii* in British coin hoards

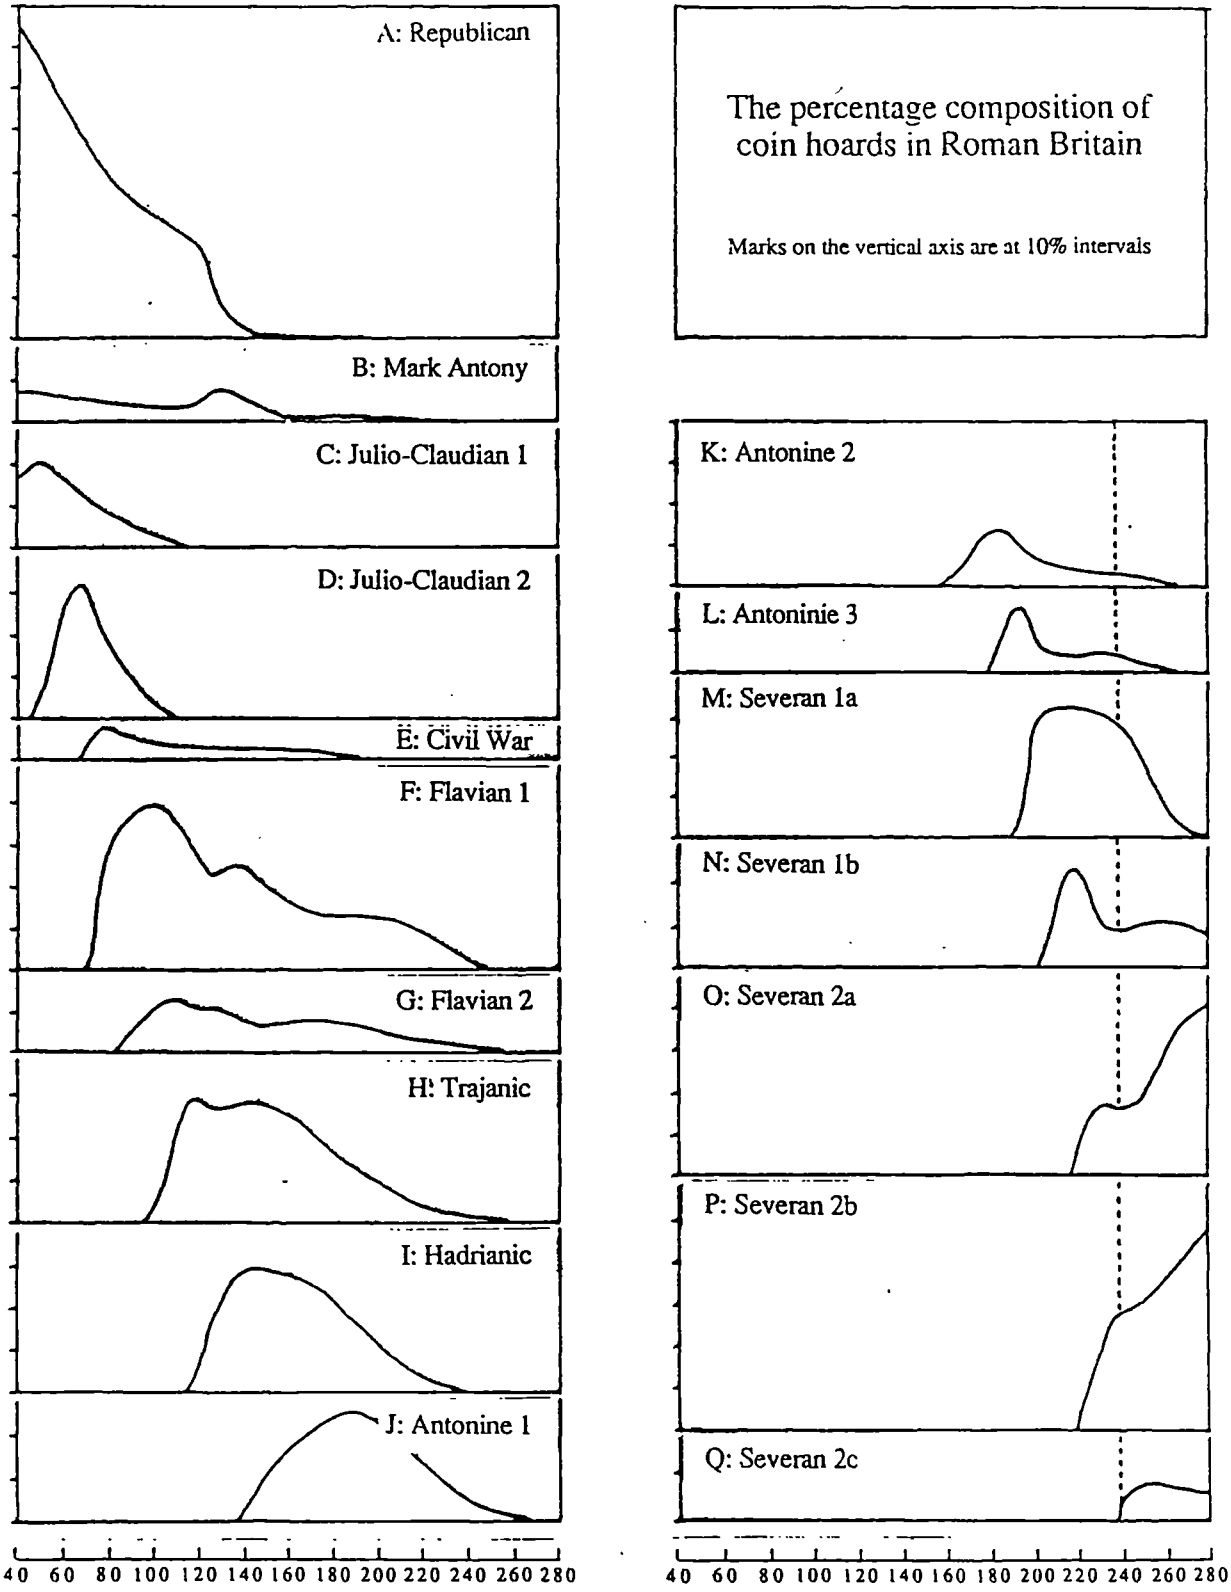

Fig. 24.06 The proportional content curves for each *denarius* group (A-Q)

2.43 Variability in hoards and its meaning

The preceding section has demonstrated that the *denarius* hoards of Britain do have a fairly regular structure. There is such a thing as the 'normal hoard'. However, the graphs did not show every hoard of each particular date to be totally uniform. Variation around the norm still exists, not all the points on the graph corresponded to a smooth line. The question posed here is what does this background variation mean and does it have any significance ?

First a chronological change in the degree of uniformity can easily be shown by examining side by side two of the hoard composition graphs (fig. 24.02 & 24.01). The first, of *denarii* up to Trajan, shows a tightly clustered line. This demonstrates a high degree of homogeneity during this period (c. AD 120-230). However, the earlier graph of *denarii* up to Vespasian shows slightly more variation (c. AD 100-190). So it appears that variation in the uniformity of hoards has a chronological dimension. So what does similarity/dissimilarity in hoards mean?

Roman *denarii* entered Britain for a number of reasons. Some may have been to pay the army and the provincial administration, whilst other may have arrived in exchange for exports to the continent. The balance between these and other possibilities is not known and possibly not knowable. However, enter Britain they did. Let us take a hypothetical example: the arrival of the new *denarii* of Hadrian. Some may have been directly shipped to the North of Britain and the provincial capital of London for regular state expenditure, whilst others may have been issued in irregular localities, such as wherever Hadrian spent the night in his brief tour around the country. From their release into circulation, transactions with other individuals would have slowly spread their distribution beyond the issuing points to other areas of the province. This picture is entirely conjectural, and yet it serves to demonstrate that whatever function coinage is serving, whatever the mechanism by which it is put into circulation, it has to enter somewhere, from whence it diffuses. This is expressed in fig. 24.07.

In a circulation pool to which a new issue is added, initially there will be a geographical inequality in the distribution of the coins. Slowly, as transactions and mixing takes place, these coins will have a wider and wider distribution. If there were no new injections of money then eventually the circulation pool would become totally uniform, with the only variation in it being due to random chance. The faster the velocity of circulation of coinage, the quicker this smoothing out would take place. However, the Roman monetary system was not comprised of single issues with long pauses in between: the system was far more dynamic with new issues being minted virtually all

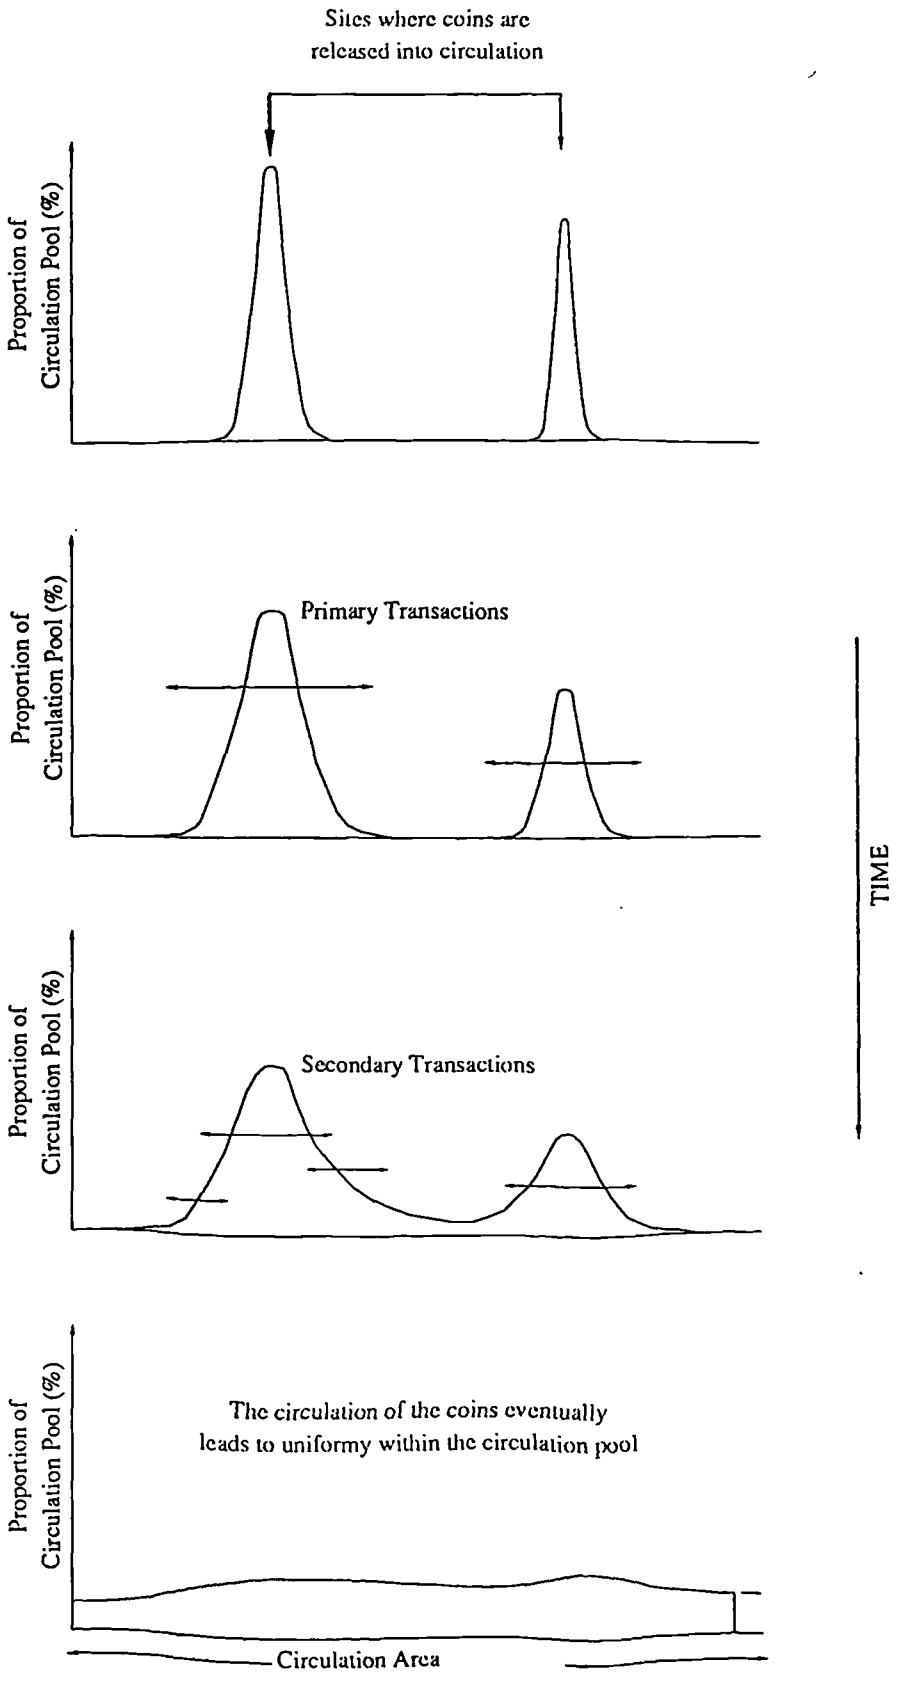

Fig. 24.07 The geographical spread of coinage after issue

the time. Once one issue had been entered into the system a new one would start. This means that a state of equilibrium in the circulation pool is never quite reached.

If coin hoards are a slice of the circulation pool, albeit selected by denomination, then their similarity to each other or dissimilarity would provide an index of the degree of irregularities in the pool. One way we would interpret our observations would be:

Observation	Interpretation
Hoards with variable composition	Coins are circulating slowly and/or New issues are continually being produced
Hoards with uniform composition	Coins are circulating very quickly and/or No new issues are coming out

If we could quantify this somehow, then we might have at our disposal a second means of examining the velocity of circulation of coinage, though one which has certain advantages over coin wear. One question raised in the coin wear analysis was whether the wear had been created by the circulation of that coin in Britain, since it might have been reflecting much broader inter-provincial trends. The advantage of the hoard analysis is that unless the hoard has been buried very far from its home, its structure is more likely to have a direct relevance to the situation in Britain than wear.

2.44 Quantifying variability: Cramer's Contingency Coefficient

If we were comparing just a couple of hoards to see if their composition was similar, then an obvious method to be used would be the chi-squared test. However, here we have a larger number of cases spread out chronologically. What we want to do is look at the hoards for each decade and measure the variation in them. As this is the initial study simply to see if such variation exists, what we require is an established statistical test. The test to be used is a measure of association of data in a contingency table. It is called Cramer's Contingency Coefficient (Φ). The value of the statistic is one if all the cases (hoards) bear no relationship to one another, and it is zero if all of them are exactly the same.

Table 2.41 shows a contingency table containing the four *denarius* hoards with suitable data from the 130s. The data has been grouped into four categories based on the groups outlined above in section 2.2.

The test statistic looks at the actual number of coins in each group in each hoard and compares them with the expected number had all of them been drawn from the same

general population. From the test statistic Cramer's contingency coefficient can be derived. A full introduction to the test is given in Appendix 2.43.

Table 2.41: *Denarius* hoards of the AD 130s represented in a contingency table

	Ref.	Name	Date	B-F	G	H	I-J	Total
Hoard 1	C 261	Weston	136	0	1	7	4	12
Hoard 2	S 114	Mallerstang	136	18	22	65	33	138
Hoard 3	C 236	Swaby	137	52	37	48	41	178
Hoard 4	S 037	Carlisle	138	13	15	19	15	62
Total				83	75	139	93	390

In the case of the coins from the AD 130s the value of Φ was 0.0224. Since this is close to zero, this suggests a very high degree of similarity between the hoards. We can proceed to do this analysis for all the other decades from the 40s to the 280s. The results are shown in Table 2.42.

Table 2.42: Cramer's contingency coefficient values for *denarius* hoards

Date Range	Φ	T	q	No. of Hoards	Date of Hoards
40s	0.1703	101.64	3	5	43.6 ±2.6
60s	0.0110	3.56	3	3	60.0 ±0.0
70s	0.2219	75.25	4	4	76.0 ±2.3
80s	0.0101	7.80	3	3	85.3 ±2.9
90s	0.1248	16.22	3	3	97.0 ±2.6
100s	0.0133	2.51	2	2	107.0 ±0.0
110s	0.1344	43.96	4	4	117.8 ±0.4
120s	0.0860	78.95	4	9	123.0 ±3.3
130s	0.0224	26.27	4	4	136.7 ±0.9
140s	0.0804	37.65	4	7	144.1 ±3.0
150s	0.0227	40.44	4	7	154.7 ±3.4
160s	0.0164	39.92	4	6	164.0 ±3.3
170s	0.0280	78.14	4	10	173.1 ±3.4
180s	0.0119	51.23	4	9	184.5 ±2.6
190s	0.0199	47.82	4	5	195.0 ±1.0
200s	0.0154	99.05	4	4	206.7 ±2.6
210s	0.0638	133.91	4	4	214.2 ±2.2
220s	0.0130	146.12	4	11	226.3 ±2.2
230s	0.0755	478.79	4	4	234.0 ±3.6
240s	0.0255	51.96	3	3	245.7 ±4.0
250s	0.0111	26.80	3	3	258.3 ±1.1
260s	0.0871	199.64	4	5	261.8 ±4.0
270s	0.3304	67.40	4	11	272.1 ±2.7
280+	1.0000	196.00	3	3	290.0 ±8.6

2.45 Interpreting variability

This information has also been displayed graphically in figs. 24.08-09. Together with the value of Φ, other information has been presented on these graphs. Fig. 24.08 shows the number of hoards looked at in each decade. Where the number of hoards is larger, the more reliable the statistic is going to be. Therefore one might note with caution the degree of similarity of the hoards in the 60s, 80s, 100s, 240s and 250s. Another factor which would bias the value of Φ would be the dates of the hoards. For example, a decade with five hoards all of one year is bound to show more similarity than a decade

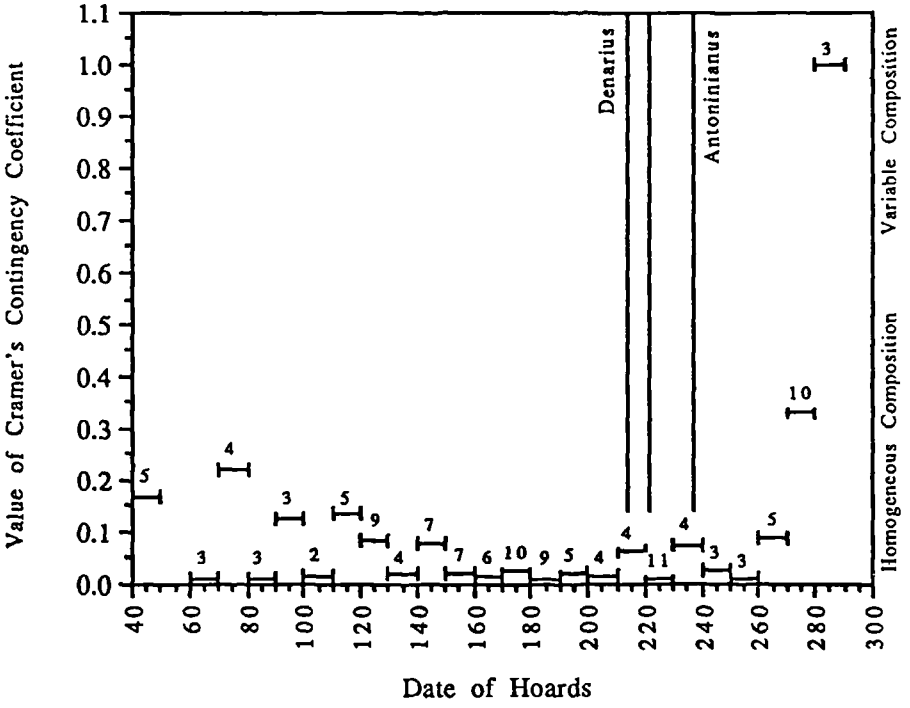

Fig. 24.08 The similarity of *denarius* hoards: sample size and 10 year blocks displayed

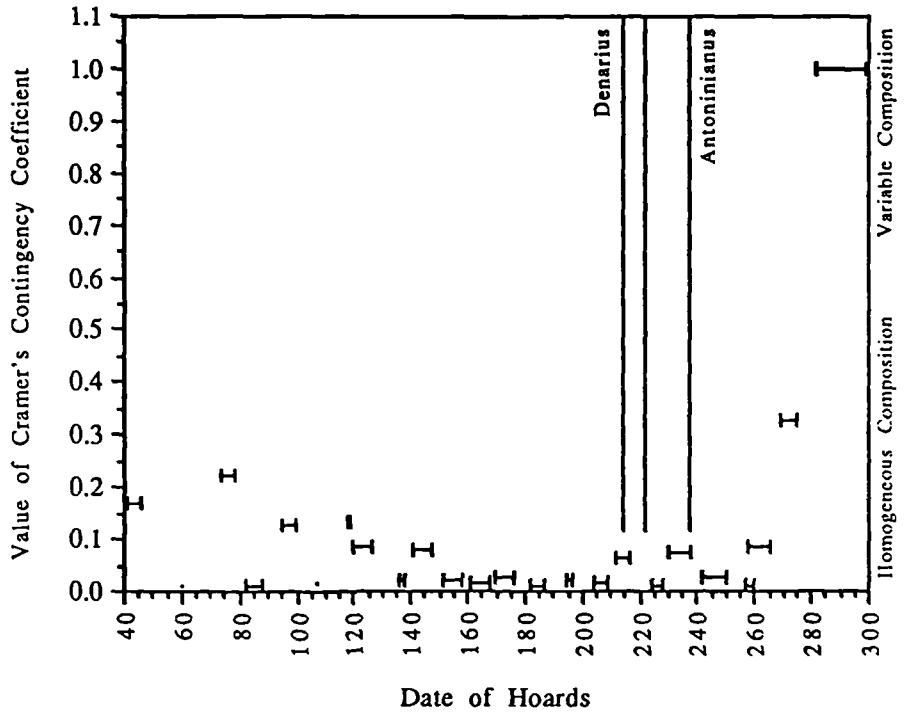

Fig. 24.09 The similarity of *denarius* hoards: standard deviation of date ranges shown

where there were five hoards spread evenly throughout the period. One simple way of demonstrating the spread of dates in the samples of any particular decade would be to present the standard deviation. Any particular clustering would show by a standard deviation of less that about ± 3.0 years. This actual value is shown on fig. 24.09 using error bars. Again the values that this means we must note with caution are those of the 60s, 100s, 110s, 130s, 190s and 250s, all of which are about ± 1 or less. With these problems in mind let us look at the general trends of the graph.

1. Invasion to mid second century

   No systematic picture emerges: some periods show very similar hoards whilst others show more diversity. However, it should be noted that all three of the low values are cases of small sample size or narrow date ranges. All we can really say is that the hoards are generally more dissimilar than in the following period.

2. Mid second century to early third century

   Here the hoards are consistently very similar, suggesting a high rate of circulation. This fits with the coin wear data which suggested that from the early second century onwards a consistent increase in the rate of circulation could be observed.

3. Early to mid third century

   During the period where the *antoninianus* was introduced, given up and introduced again the hoards show no tremendously systematic picture, except that the hoards were probably more diverse in composition than in the preceeding period, suggesting a slowing down in the circulation rate of *denarii* .

4. Mid third century onwards

   From the 260s the number of *denarii* in hoards is very small anyway, and those samples that do exist are very diverse in composition largely due to the very small numbers involved.

The results are not entirely satisfactory. We can see that there are chronological changes in the similarity/dissimilarity of hoards. This tells us that an analysis of variation in hoard structure is probably worthwhile as the variation is not entirely due to chance. Were it entirely a random effect then no chronological pattern would have been expected.

The problems with this method is its reduction of the data. All the variety of hoards within a decade are compressed into one statistic. This statistic is also prone to variation caused by the dates of the hoards and the size of the sample of hoards. Also there is a fair degree of subjectivity in the division of the data into coin groups; changing the groupings alters the value of Φ slightly. Finally, within that 10 year block changes might be taking place which the resolution of this method makes it impossible to detect.

2.46 Conclusions

In this section we have established a background picture of how *denarius* hoards in Britain are made up. This gives us for the first time a broad idea of the changing composition of the money in circulation.

It was noted that though the general picture was created using an average of all the individual hoards, naturally each individual hoard does not necessarily correspond precisely with this. Each hoard is slightly different. That difference must reflect something, be it random sampling variation, selection in hoarding, or else regional differences in the circulation pool.

It was considered that the faster coinage moves around the system the fewer irregularities would exist in the circulation pool and the closer to the general picture each individual hoard would be. The analysis of coin wear had shown a variation in circulation rates, so a chronological dimension was looked for in hoard similarity/dissimilarity.

Some chronological differences were found, using Cramer's Contingency Coefficient, indicating the period of highest similarity was the mid to late second century. This corresponded to the period of increased circulation rates indicated by the wear analysis. However, the rest of the study was not particularly enlightening. Nonetheless it served to show that the degree of variation in hoard composition might be a useful source of information, though a more 'tailor-made' technique would be required to obtain the information, one which looked at individual hoards rather than groups of hoards. Such a technique is developed in Section 2.5.

2.5 Hoard Structure

The aim of this section is to expand upon some of the ideas introduced in section 2.4. Here we want to examine in detail hoard structure. Two new methods are developed to quantify the structure of hoards (2.51 to 2.54). This information is then analysed for chronological (2.55) and geographical (2.56) trends; both of which are found.

2.51 Introduction

Reece's analysis of Severan hoards (Reece 1974a, 81) noted that some hoards had a higher proportion of new coins in them than others. From the examples that he used, this appeared to be related to how far away from a source of supply a hoard was accumulated. Thus Carrawburgh had the highest proportion, which immediately tempted an association with military pay. Bristol had the next highest, while other sites, with fewer and fewer Severan coins, were seen as representing stations further and further along the exchange network of *denarii* until finally the most obscure rural site was eventually reached. This was simply an idea offered on the basis of a very small number of hoards. Nonetheless it is suggestive of the potential information which hoard structure might contain.

The analysis did however have a number of weaknesses. The idea itself was interesting and the results potentially very informative, but in this case there were some problems with its execution. The principal problem was that the hoards were not all of one date, but rather ranged over a period of a decade and a half. Since Septimius Severus' coin took time to come into circulation then we would expect later hoards to contain a higher proportion of his issues than earlier hoards, and as the table below shows this is precisely what we see here. The time taken for Severan coins to enter circulation far better explains the variation in this data than Reece's supply model. The occasion for such a steep rise in the number of his coins late in his reign may have been his visit to Britain (208-211), where he was said to have brought with him a lot of money (according to Dio 76, 11, 1).

Table 2.51: Five Severan hoards

Hoard	*T.P.Q.*	*% Coins of S. Severus*
Handley Wood	194-195	0.5
Silchester	194-195	0.8
Portmoak	196-197	1.9
Bristol	208	33.0
Carrawburgh	210-212	73.0

Despite this unfortunate finding, this kind of question about whether hoard structure can tell us anything about coin supply is one which should be pursued. However, we are forewarned that this requires a finer chronological precision than simply that of an emperor's reign.

2.52 How can we illustrate structure?

Looking at one particular chronological group of hoards, as Reece did, meant that the quantification of 'structure' was easy, one simply took the proportion of coins of Septimius Severus in the hoard as the variable. However, we need a method which can be applied over a far wider time-span than Septimius Severus' reign. Structure can be defined in many ways; in the fourth century dividing by the mint marks can have interesting results. Here the major differences in *denarius* hoards are due to their age profiles. This being the case, one way of visually expressing hoard structure would be a cumulative frequency graph. An example, the Parwich Hill hoard, is shown in fig. 25.01. For the moment ignore the 'white' line, and just examine the 'black' curve for the hoard itself. The construction of the curve is very straight forward. The hoard contained about 80 *denarii* , 79 of which were well recorded. The TPQ for the hoard was AD 161-180. The coin numbers are transformed into percentages then cumulative percentages. This information is then displayed on a graph (fig. 25.01) which shows what proportion of the hoard is earlier than a particular date. For example we can note that about half the assemblage dates to before AD 110. Naturally, by the time the terminus post quem of the hoard has been reached, 100 % of the coins in the hoard are represented.

Table 2.52: The Parwich Hill hoard, data for fig. 25.01

Emperor group	Number of coins	Percentage	Cumulative Percentage	Date Range
Mark Antony	1	1.53 %	1.53 %	40 BC to 31 BC
Julio-Claudian 1	0	0.00 %	1.53 %	37 BC to AD 41
Julio-Claudian 2	2	3.08 %	4.61 %	AD 41 to 68
Civil War	1	1.54 %	6.15 %	AD 68 to 69
Vespasianic	5	7.69 %	13.84 %	AD 69 to 81
Domitianic	13	20.00 %	33.84 %	AD 81 to 98
Trajanic	22	23.08 %	56.92 %	AD 98 to 117
Hadrianic	23	24.61 %	81.53 %	AD 117 to 138
Antoninus Pius	9	13.85 %	95.38 %	AD 138 to 161
Marcus Aurelius	3	4.62 %	100.00 %	AD 161 to 177
TOTAL	79	100.00 %		

If each *denarius* in the hoard could be dated to an individual year, then this curve could be made even more precise. However, the emperor groups above have been used because most of the data will not sustain a more detailed analysis, therefore the temptation to use finer date ranges would only have reduced our potential data-base.

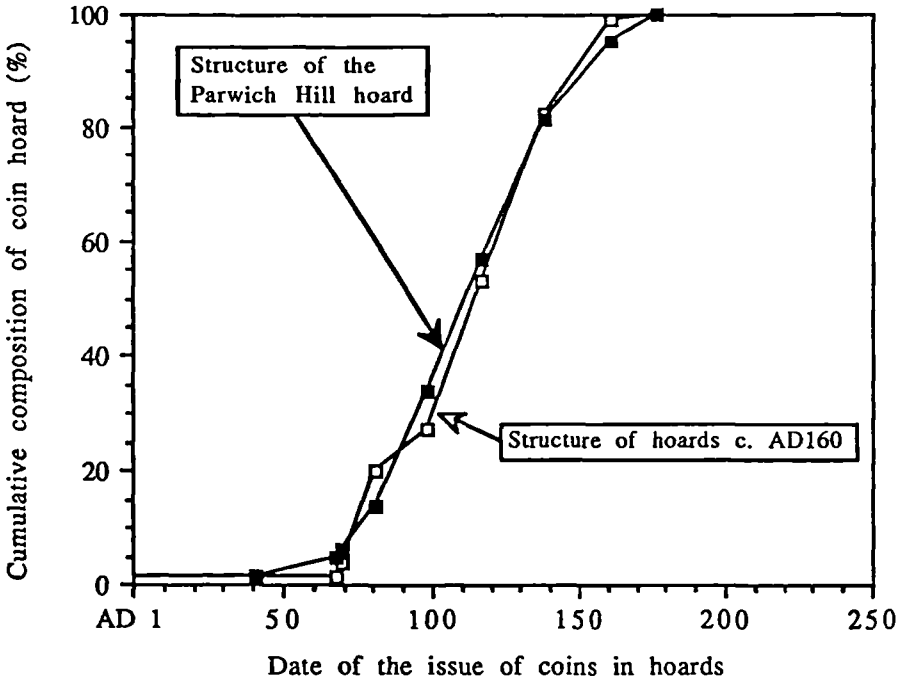

Fig. 25.01: Hoard structure of the Parwich hoard: an almost normal hoard

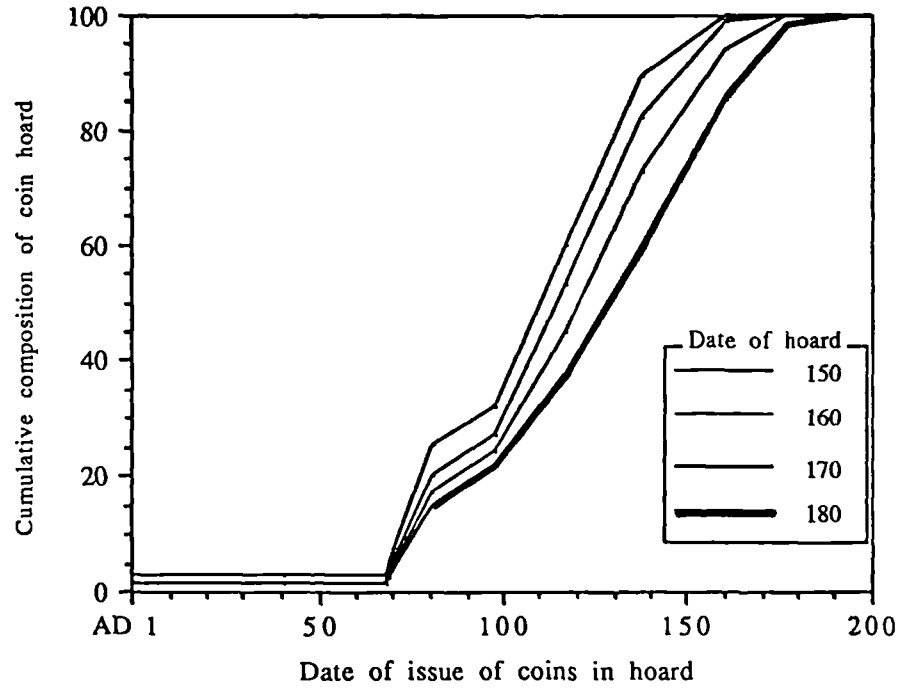

Fig. 25.02: Normal hoard structure from AD 150-180

Secondly, whilst individual issues may alter in date as numismatic studies further our knowledge, the dates of Emperors are reasonably fixed points and unlikely to change.

2.53 Structure and the 'normal' hoard

We now have a way of visually describing hoard structure. Not only can graphs like this be used to describe the structure of an individual hoard, but the data from fig. 24.05 (Appendix 2.42) can be taken to represent the structure of the 'normal hoard' of any particular date as well. This means it is possible to compare individual hoard's structures with the average hoard structure of any particular date.

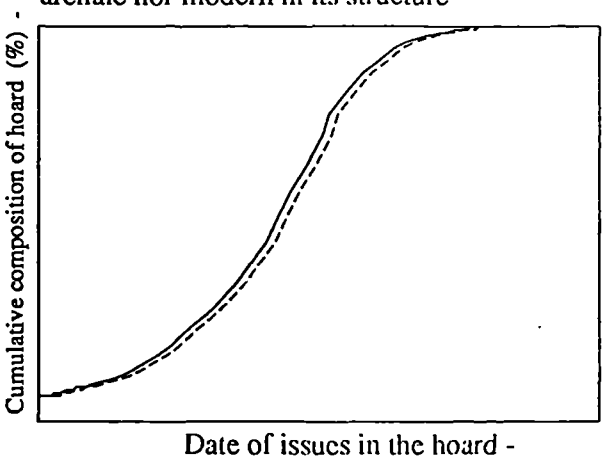
The Parwich Hill hoard dates to some time after AD 161-180. Fig. 25.01 compares its structure to that derived from our bench-mark of the date *c.* 160, the earliest possible date of the hoard. The two curves are very similar: of course there are slight differences, but it does tend to suggest that the Parwich Hill hoard is fairly 'normal' in its own right; it shows no marked deviation from our bench-mark, though the similarity to AD 160 rather than 170 or 180 suggests that the hoard was buried earlier rather than later within its *terminus post quem* range.

Here we have compared the Parwich Hill hoard with the structure of 160, however in principle it could be compared with the normal structure of any particular date; the curves for 150, 160, 170 and 180 are shown in fig. 25.02. This is where we start using our bench-mark as a metrological device. Individual hoards can be compared against it to see it their structure is 'normal' or not. But far more than this simple distinction, we can look for specific types of deviation. Here the concept of 'archaic' and 'modern' hoards is introduced. An archaic hoard is simply a hoard which contains a higher proportion of older coins in it that a hypothetical 'normal' hoard of the same date; and a modern hoard is a hoard which contains a higher proportion of newer coins than the 'normal' hoard of that date. This sounds very straightforward, but actually defining a variable to measure it is not quite so simple. First let us examine how an archaic or modern hoard would reveal itself. The four possibilities are shown in fig. 25.03. These illustrations are all versions of that above drawn for the Parwich Hill hoard. The individual hoard structure is compared against the normal hoard structure of the same date.

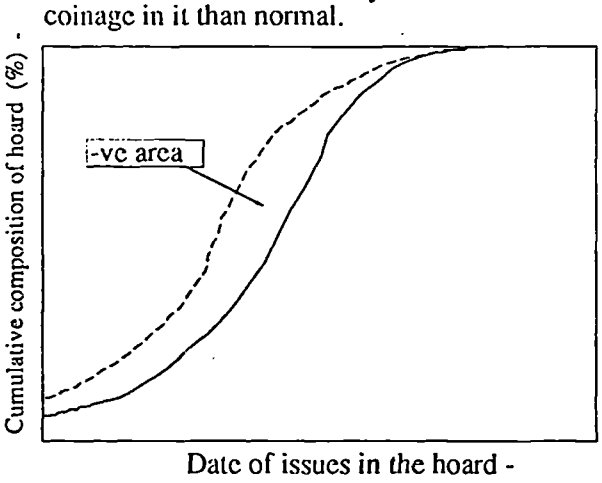
CASE A: The Normal Hoard

Here the structure of the specific hoard follows very closely the normal pattern, so that there is no gap between the lines.

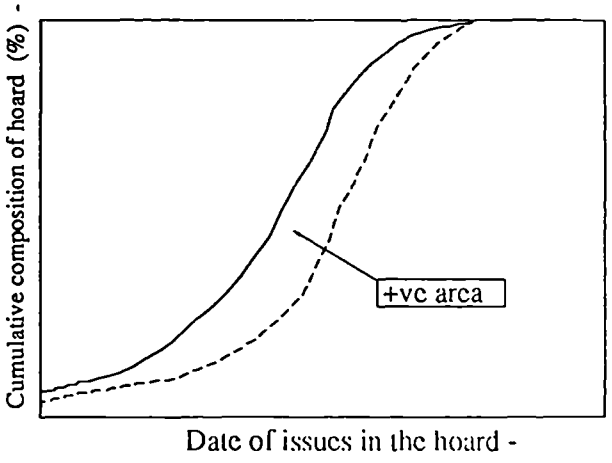
Case A
A hoard which is neither relatively archaic nor modern in its structure



Case B: ARCHAIC
A hoard which has relatively more older coinage in it than normal.



Case C: MODERN
A hoard which has less older coinage in it than normal.



Case D: AVERAGE but variable
A hoard which has relatively more older and newer coinage in it than normal; but little in between.

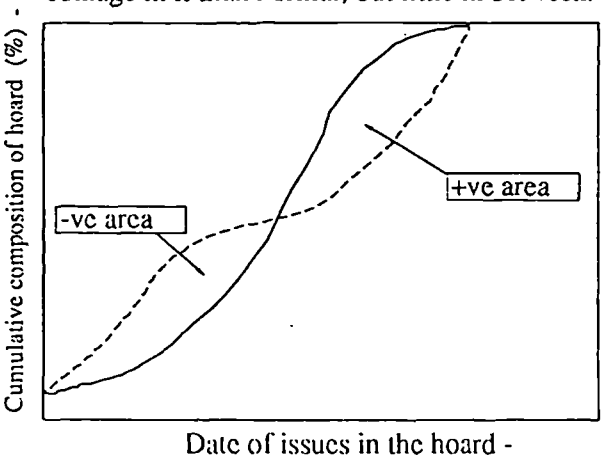


Fig. 25.03: Four models of hoard structure

CASE B: The Archaic Hoard

Here, because there are proportionally more older coins in the hoard, the specific hoard indicated by the dashed line lies above the normal hoard curve. The gap between has an area. The more archaic the hoard is, the greater this area will be.

CASE C: The Modern Hoard

The opposite is the case with a modern hoard. Because there are proportionally more newer coins, the curve is depressed until the final stages where it catches up with the normal hoard structure. Again the area between the two lines will be greater the more different the modern hoard is, though this time the area is on the opposite side of the normal curve.

CASE D: The Average but variable hoard

Here we have a mixed situation: a hoard with a lot of older coin, and a high proportion of newer coin, though few of the intervening years. On average therefore it is neither archaic nor modern, the two areas on either side of the curve balance themselves out. However, the hoard is still divergent from the norm.

A good example of an Archaic hoard is given to emphasize the point. The Falkirk hoard is very untypical in its construction. Its latest coin dates to AD 230, though it is far more like a hoard of the 180s. Fig. 25.04 shows the large area between the normal and Falkirk curves.

2.54 The quantification of structure

By giving these areas above and below the line different signs we can create a series of variables which define structure in relation to our bench-mark. If we make areas above our bench-mark curve negative, and areas beneath the curve positive, then archaic hoards would have a negative net area value, and modern hoards a positive net area value. Our Case D hoards would appear close to zero, since the areas on both sides of the normal curve would balance themselves out. In order to cater for our Case D hoards, a second variable can be created: the gross area value. Here the areas on either side of the curve are added together irrespective of their sign.

Definitions:

Gross Area Difference (GA Value)

The absolute total area between the Specific hoard curve and the 'normal' hoard curve.

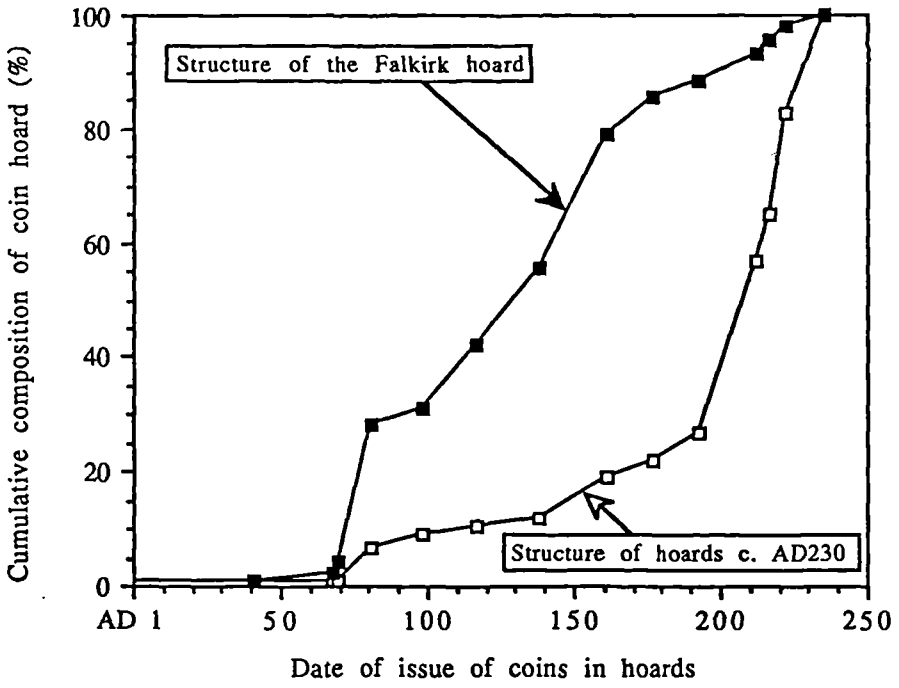

Fig. 25.04: Hoard structure of the Falkirk hoard: an archaic hoard

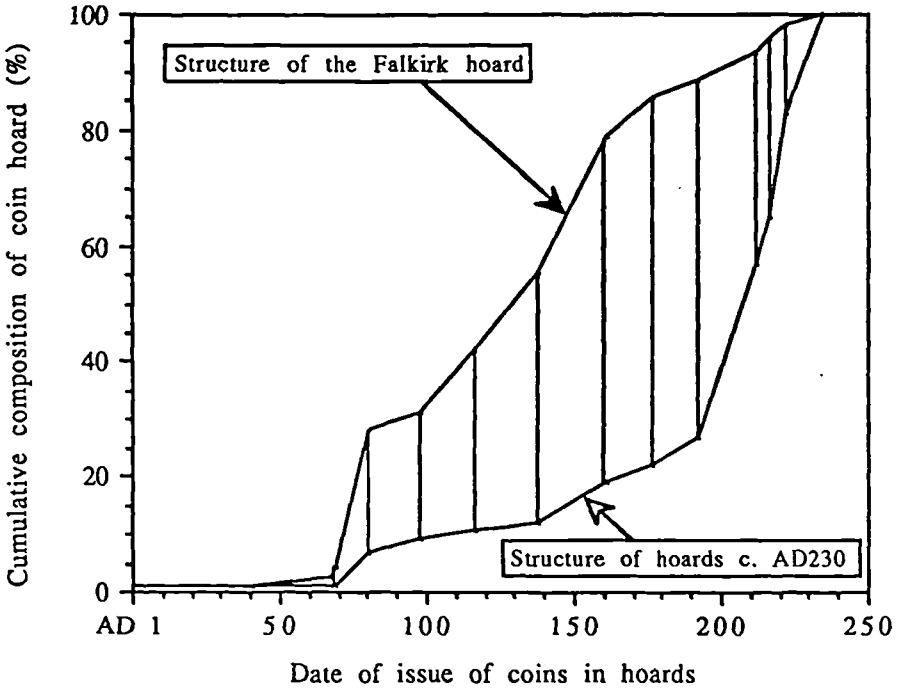

Fig. 25.05: The calculation of hoard structure: the Falkirk hoard

Net Area Difference (NA Value)

The total area between the 'normal' and specific hoard curves beneath the 'normal' hoard line less the area above the 'normal' hoard line.

Table 2.53: Gross area and net area values in each type of hoard

Hoard type:		Gross Area Difference	Net Area Difference
Case A:	A normal hoard	0	0
Case B:	An archaic hoard	+	-
Case C:	A modern hoard	+	+
Case D:	An average but variable hoard	+	0

These values can be calculated by dividing the area between the curves into segments. This has been shown for the Falkirk hoard in fig. 25.05. The area of each individual segment can be measured and the results of all added together to form the GA Value, or else the sum of all the archaic areas taken away from all the modern areas to give the NA Value. In the case of the Falkirk hoard the Gross Area Value was 6283, whilst the Net Area Value was -6283. The negative value of the Net Area indicates it to be an extremely archaic hoard.

This would all be far too time consuming to calculate by hand for each hoard, so the process has been converted into a computer program. The mathematical and geometric basis of it is given at the start of Appendix 2.51, followed by a description of the program and the program itself. The package looks at a specific hoard and contrasts it against the normal structure of the same date and calculates the Gross Area and Net Area values.

There are two different ways of defining how archaic or modern a hoard is. The Falkirk hoard provides a good illustration of this. Either you can look at the hoard and compare it to the structure of hoards at that same date and get in Falkirk's case a very large negative value for the Net Area Difference (indicating it is massively archaic). Or else one could search through time to see at which date the Falkirk hoard would have been happiest. The Falkirk hoard is in fact most like a hoard of around 182, though it must have been deposited in the 230s. This means that its structure is about 48 years behind the times. The second method has the advantage that it conveys an immediate impression of the degree of antiquity or modernity shown by a hoard which a value of the Net Area Difference does not. However, the Net Area Difference is perhaps a better indicator as it compares a hoard with its immediate chronological contemporaries. In the following both methods have been used.

Definitions:

METHOD 1: This is the straightforward quantification of the Net Area Difference at the TPQ date of the hoard.

METHOD 2: This is the calculation of the 'best fit date' of the hoard, as judged by the date at which the Net Area value is closest to zero. The difference between the best fit date and the TPQ date of the hoard is then calculated to see if the hoard is archaic or modern. This result is expressed in years. It is positive if the hoard is modern and negative if archaic.

It would be timely here to look at a few case studies where both these methods and the problem of TPQ ranges can be worked through:

Table 2.54: Hoard structure analysis, worked examples

				Method 1	Method 2	
Hoard Name	Type	TPQ	best fit date	best fit date within TPQ	difference	
Falkirk	Very Archaic	230	182 NAD = 26	230 NAD = -6283	-48 years	Fig. 25.06
Mildenhall	Normal	80-85	80 NAD = 59	80 NAD = 59	0 years	Fig. 25.07
Dewsbury	Modern	117-139	151 NAD = -35	138 NAD = 1186	13 years	Fig. 25.08
Parwich	Slightly Archaic	161-180	157 NAD = -35	161 NAD = -238	-4 years	Fig. 25.09

Fig. 25.06 shows the change in value of the Gross Area Difference through time for the Falkirk hoard. At the *terminus post quem* date for the hoard the deviation is great, and as one would expect as we move back in time to the 180s the deviation decreases. The net area deviation reaches zero in 182; however, the gross area difference reaches a minimum slightly later in date: around 185. The two ways of measuring the 'best fit date' (henceforth BFD) do not always absolutely agree. Though rarely is there more than a couple of years difference. Throughout this analysis the BFD has been defined as when the net area value is closest to zero. Both our Method 1 and Method 2 results give us large negative values indicating the antiquity of the hoard.

In the case of the Mildenhall hoard (fig. 25.07) our data does not provide us with a single date *terminus post quem* , but rather a date range. In this case we have to decide which section of the *TPQ* range we test the structure of the hoard against for Method 1. In practice what has been done is to test the similarity of the hoard to every date within its *TPQ* range; and the benefit of the doubt has been allowed to the hoard by allocating it to the best date within the range permitted. It just so happens that the BFD is just within the *TPQ* range, so this is taken to be the 'nominal' date for the hoard. Here the range is 80-85, and the 'best fit date' is 80.

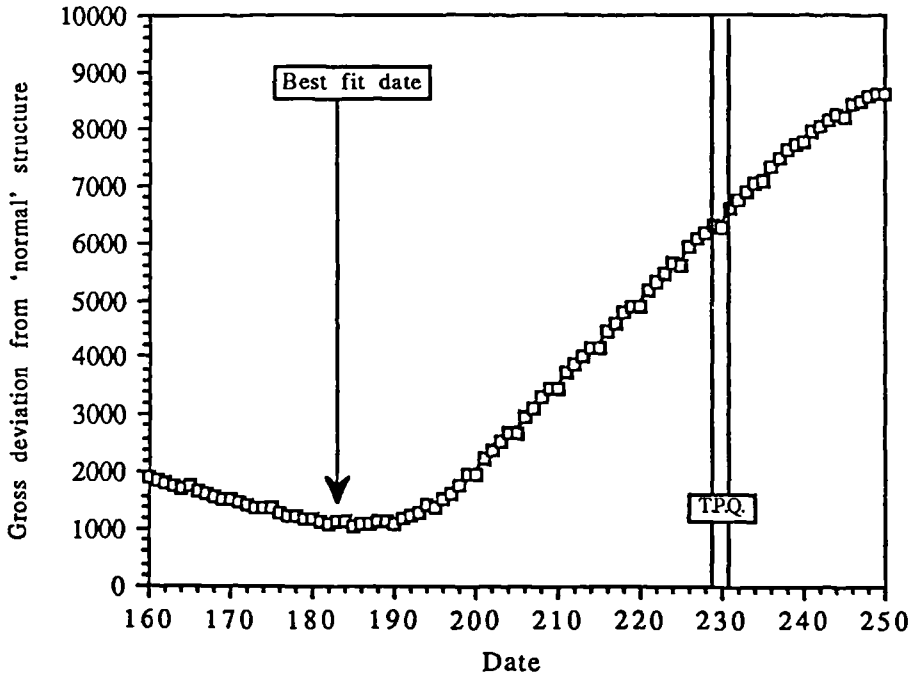

Fig. 25.06: A very archaic hoard: Falkirk (1,931 *denarii*)

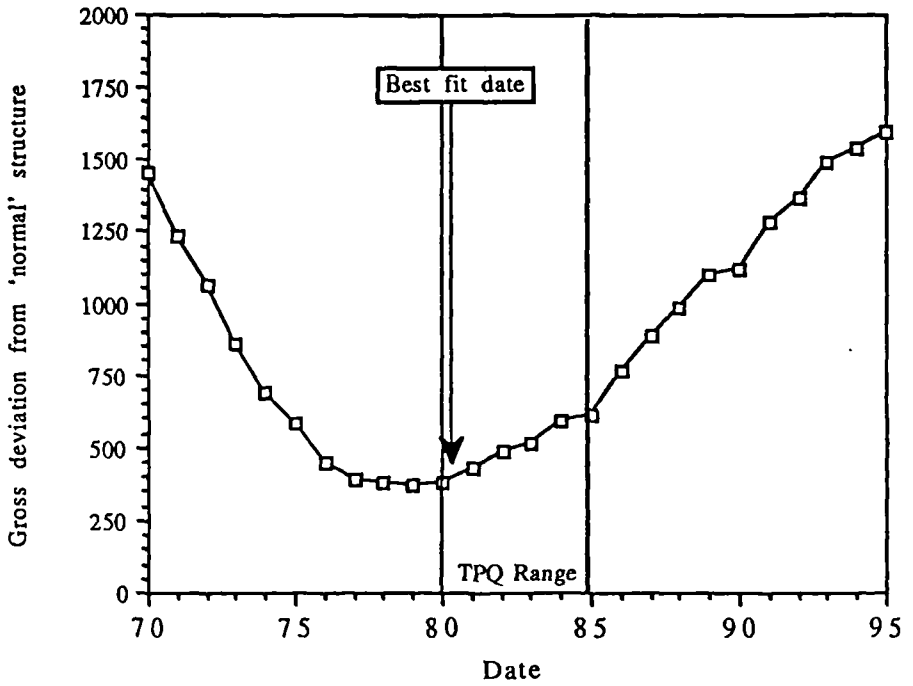

Fig. 25.07: A normal hoard: Mildenhall (277 *denarii*)

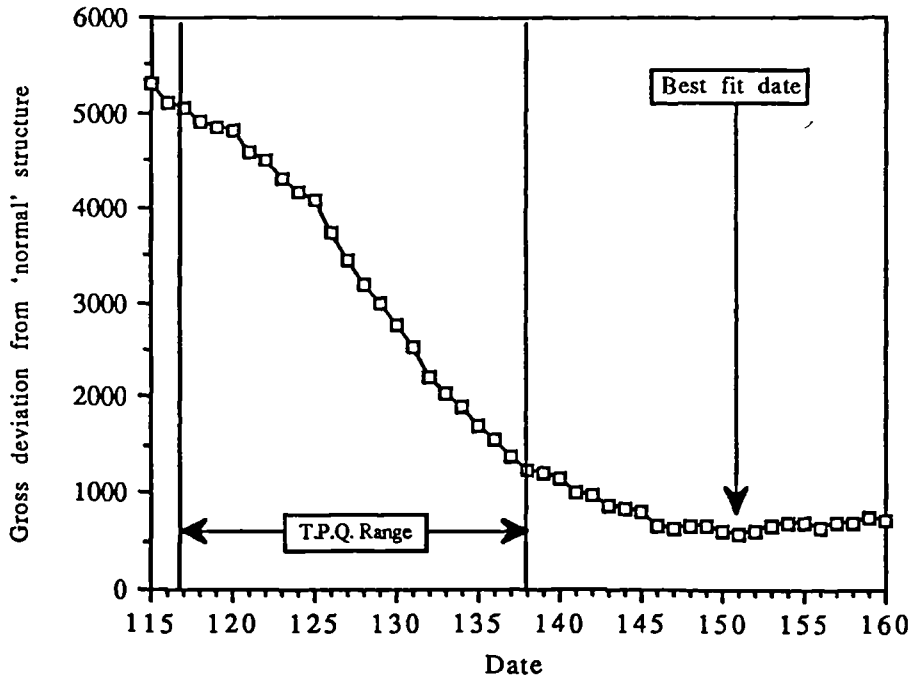

Fig. 25.08: A modern hoard: Dewsbury ((26 *denarii*)

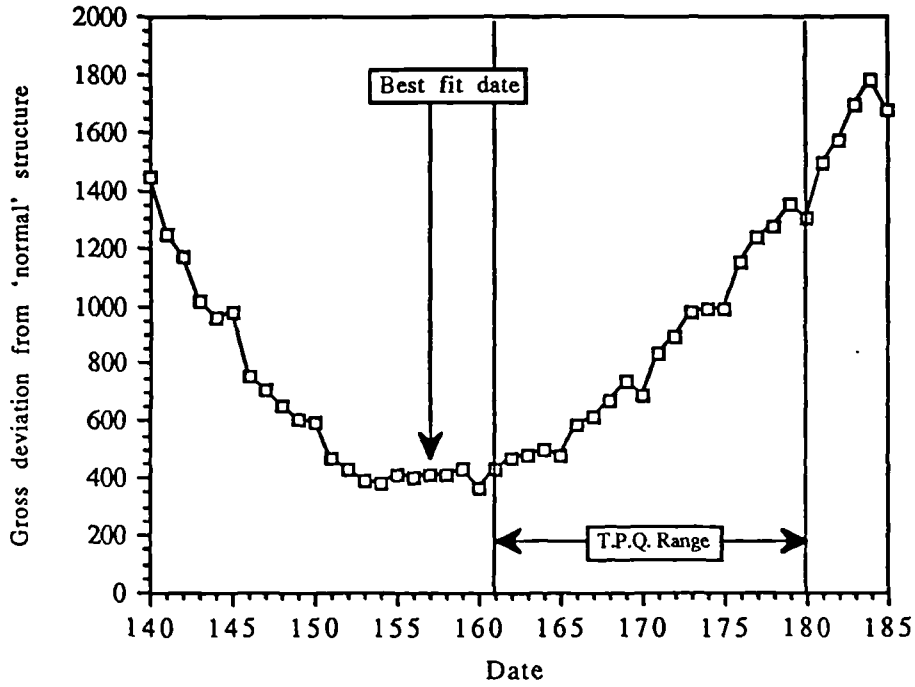

Fig. 25.09: A slightly archaic hoard: Parwich (80 *denarii*)

Mildenhall, however, is a normal hoard. In the case of an archaic or modern hoard the 'best fit date' will by definition be outside the *TPQ* range. Here the closest date to the BFD is therefore taken within the *TPQ* range given. Thus for Dewsbury, though the *TPQ* is 117-139, the BFD is found at 151; so 139 is taken as the nominal date of the hoard. The situation for Parwich Hill is the reverse (fig. 25.09). Here the BFD is found to be four years before the *TPQ* range starts, so the earliest date in the *TPQ* range is taken.

In practice this creation of a nominal date for a hoard within its own *TPQ* range had to be done with about 45 % of the hoards used in the analysis. The procedure is a useful device, but there are biases caused by it. The bench mark itself was created using all the hoards together with more than five coins in them. In the cases where the hoards had a *TPQ* range there the mid point was simply taken. Therefore when the individual hoard is tested against the composite picture which it helped to make up there is a very slight tendency for the BFD of the hoard to veer towards the mid point of the *TPQ* range. In fact only six BFDs are found within the *TPQ* ranges, so this effect on the results is minimal.

All the cases where a nominal *TPQ* has been established from a *TPQ* range are outlined in Appendix 2.52.

The raw results are outlined in Appendix 2.54.

2.55 Analysis: Chronological

Back in section 2.4 it was suggested that the more similar hoards were, the faster the circulation pool was moving around. Alas the analysis using Cramer's contingency coefficient was constrained by its comparison of hoards of different dates together in ten year blocks. This was the same weakness as Reece's analysis using Severan hoards mentioned above, since much of the variation came from chronological changes rather than anything else.

Instead of comparing one hoard directly against another of a different date, here the hoards have been tested against the general pattern of the same date. The general pattern having been formed by averaging and interpolating hoards of all dates so that a continuum has been created from the invasion to 280.

The raw results for Methods 1 and 2 are shown in figs.25.10 & 25.13. The format of each graph is the same. Each hoard larger than five coins is shown as an individual square. Those appearing above the line are modern hoards in comparison to our bench-mark. Those appearing below the line are relatively archaic. The three vertical lines are

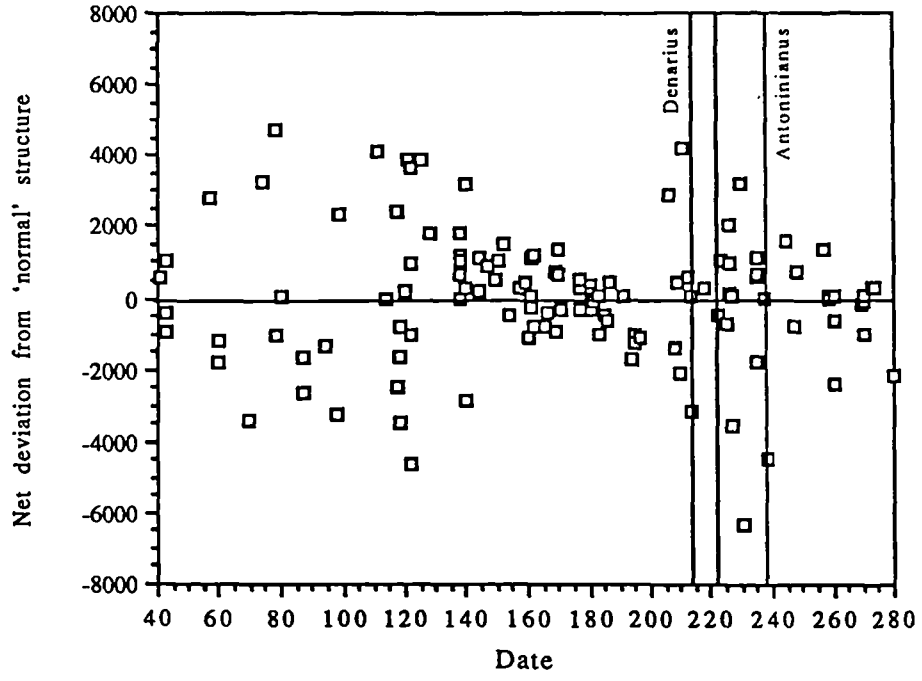

Fig. 25.10: The 'net deviation' of all the hoards against time

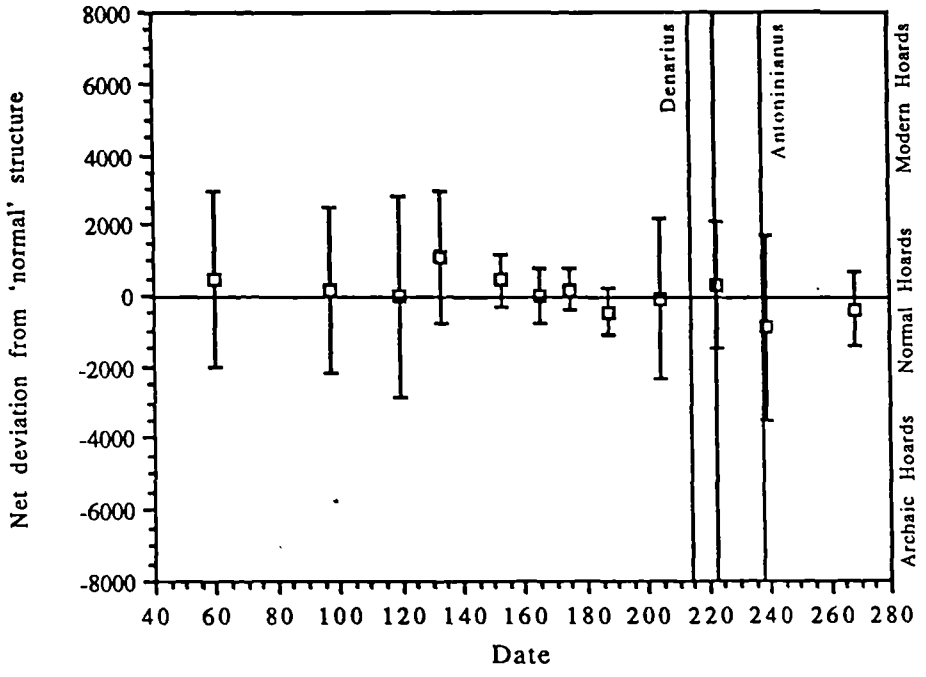

Fig. 25.11: The range of the 'net deviation' of hoards against time (1)

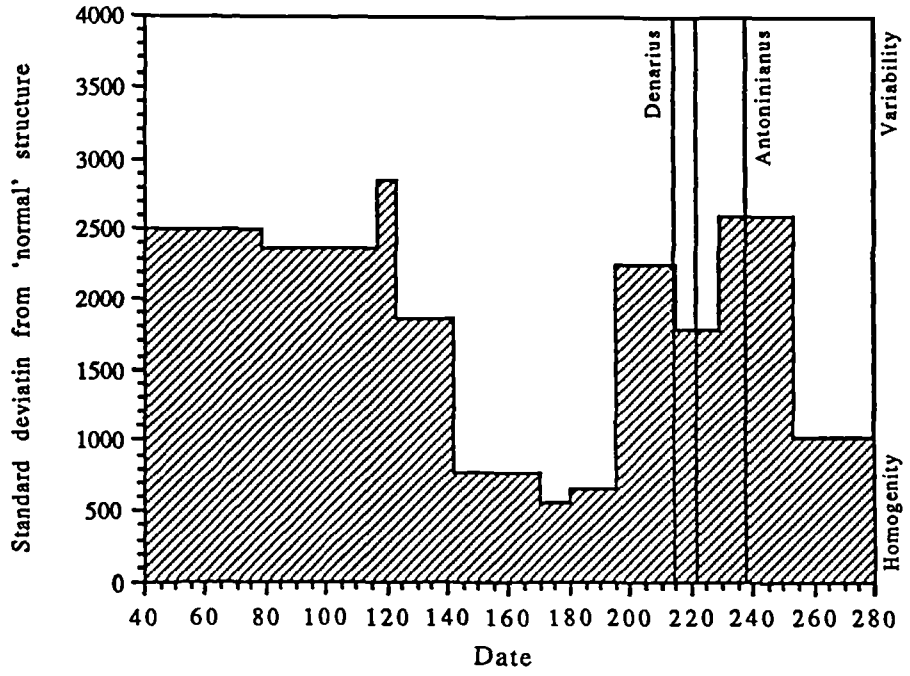

Fig. 25.12: The range of the 'net deviation' of hoards against time (2)

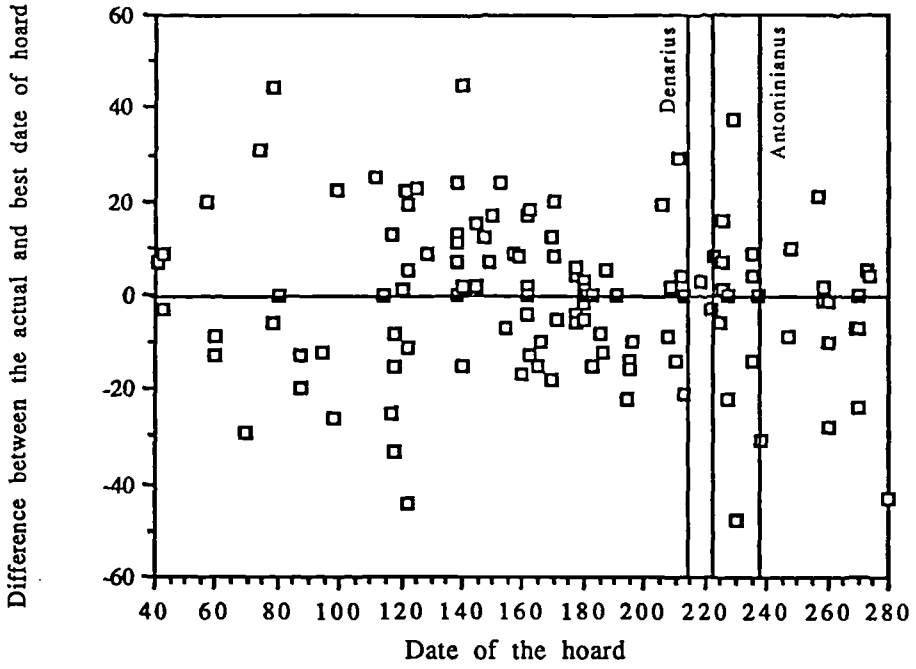

Fig. 25.13: The 'date differential' of all the hoards against time

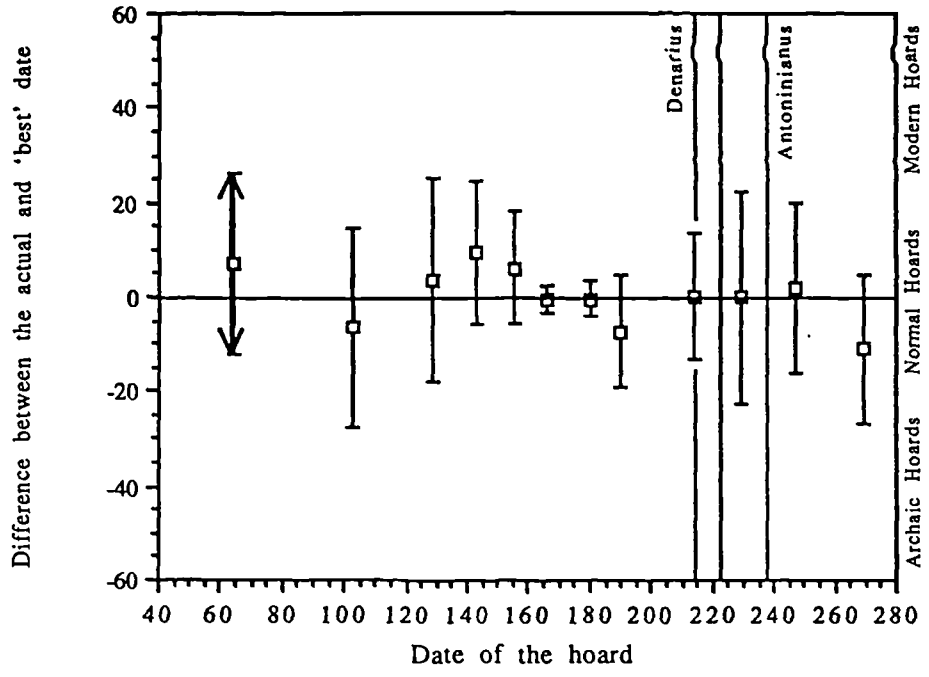

Fig. 25.14: The range of the 'date differentials' of hoards against time (1)

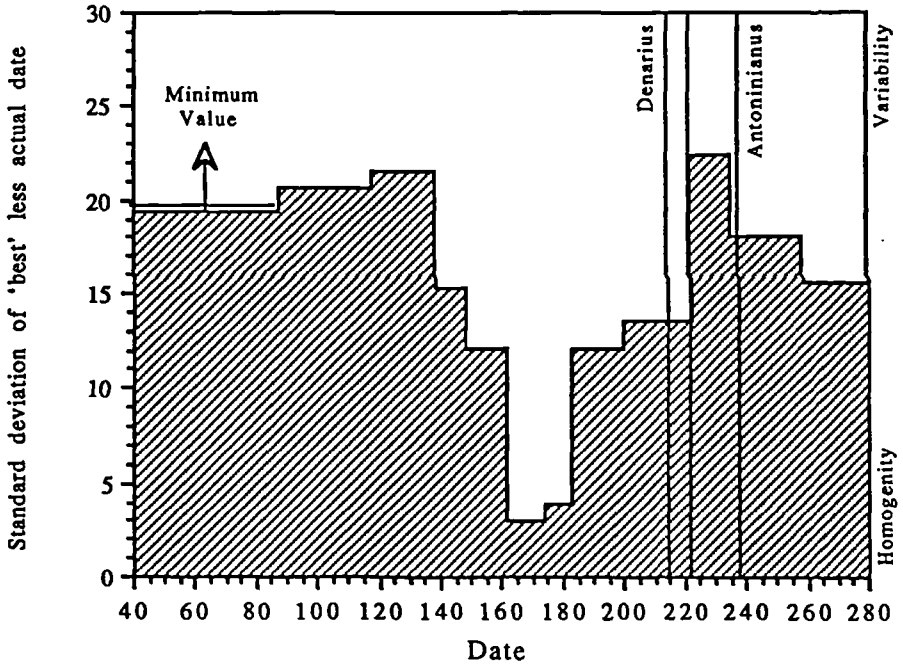

Fig. 25.15: The range of the 'date differentials' of hoards against time (2)

simply added to assist visual perception of the effect of the end of production of the *denarius* and the institution of the *antoninianus* . The first line at 215 represents Caracalla's introduction of the new coin, whilst the second and third represents the *antoninianus*' suspension from production during 222-238. However, it is stressed that all the information on the graph comes from *denarii* only.

The general trends on both the graphs are similar, suggesting that both methods of measuring the degree of divergence from the 'normal' hoard are complementary. The trends are:

Conquest to AD 80:	A growth in the variability of hoards	(velocity of circulation falls)
AD 80 to AD 120:	A sustained high variability in hoards	(velocity of circulation low)
AD 120 to AD 200	A decline in the variability of hoards	(velocity of circulation rises)
AD 200 to AD 220:	A growth in the variability of hoards	(velocity of circulation falls)
AD 220 onwards:	A decline in the variability of hoards	(evening out as production ceases)

The degree of deviation on these graphs can be summarized by calculating the standard deviation of the data over various date ranges. These values are calculated in Appendix 2.55, and shown in figs.25.11, 25.12, 25.14 & 25.15. Here the hoards have been taken in blocks of ten and the deviation over that time period calculated. The results are shown in two ways, firstly as error bars (figs.25.11 & 25.14), then as the standard deviations themselves. Unfortunately because there are few early hoards, the early similarity of hoards in the 40s and 50s is not shown up very well on the summary graphs, but can be seen clearly on the raw data plots.

The interpretation of this is that at the period of conquest we have *denarii* circulating around very rapidly, hence many of the regional imbalances in the circulation pool were ironed out leading to relatively uniform hoard composition. However, this phase did not last very long, so that by the late first - early second century hoards were very variable, indicating a slow movement of coinage around the system. Things appear to have picked up again, with hoards reaching their peak of uniformity in the mid to late second century. Then came the large Severan injection of *denarii* into circulation. This high velocity of circulation could not be sustained. The rate falls rapidly as an increased number of coins move around the system doing the same amount of 'work' as the previously smaller number did. Then finally the *antoninianus* is introduced. Hoards at this point become more similar; however, changes in the velocity of circulation need not explain everything. As noted in section 2.4, a cessation of new *denarii* put into circulation would lead to uniformity eventually being established in the circulation pool. This is exactly what we see after the takeover of the *antoninianus* . The *denarius* component of hoards slowly becomes uniform as any imbalances in the

circulation pool are removed. An alternative interpretation would be that the similarity of hoards still reflects a high velocity of circulation of *denarii* explained by the coins having a premium value over the baser *antoniniani* . I prefer the former explanation.

We now have two different models which purport to describe changes in the rate of circulation of *denarii* in Britain: the coin wear analysis and this hoard structure analysis. Is there any correlation between the two ?

The conclusions from the coin wear study were:

1. From the conquest to the early second century *denarii* slow down in their rate of circulation in Britain.

2. From the early second century to the late second century *denarii* slowly increase in their rate of use in Britain, no information beyond this date being possible from this analysis.

Both analyses therefore come to the same conclusions for this period, though both are based on very different sets of data; one on the weight of coins and the other on the structure of hoards. This strongly suggests that the models are correct. Beyond this date, the wear analysis cannot corroborate this method. So though there is a sharp increase in the diversity of coin hoards in the very late second/early third century we cannot hope to verify this with coin wear evidence unless far more large *denarius* hoards are weighed.

2.56 Analysis: Spatial

In the introduction to this section I noted Reece's idea that the structure of hoards might reveal where new coinage was entering the circulation system. As it happened the variation in his selection of hoards could be better explained by other variables such as their date; but the idea itself is nonetheless worth pursuing. We now have a variable which can tell us if a hoard is archaic or modern, so let us plot these geographically to see if any picture emerges. The data have been split up into four chronological periods of about fifty years. AD 100 and 150 have been used as arbitrary divisions, whereas AD 196 has been used since the division of the province which took place around about then may have influenced the arrival of *denarii* into Britain. The plots are very simple. They show the 'Net Area Difference' value. A large black circle represents a very modern hoard, a large white circle correspondingly represents a very archaic hoard (Eg. see Falkirk blotting out most of the lowlands of Scotland in fig. 25.19); whilst a normal hoard is a simple dot.

Map 1 Fig. 25.16 AD 43 - 99

The picture here is confused by the chronological spread and changes in troop deployment in the province. The most notable deviant hoards come from outside the South East, particularly from Yorkshire, and by dividing these up chronologically a clear picture begins to emerge.

Dating to the conquest of the South East there are three hoards from Yorkshire which at this stage was beyond the main army presence. These are the Lightcliffe & Almondbury hoards (AD 43+) both possibly part of the same hoard (cf Allen 1963); and the Honley (AD 69) hoard. All three have archaic structures. This suggests that new coinage was not being directly sent beyond the imperial frontiers at this stage.

In the early 70s all of Yorkshire came under direct Roman control and a major military centre established at York. A series of forts were also occupied in East Yorkshire along the Brough on Humber to York road. It is during this period of a high army presence that two hoards with relatively modern structures can be found: York (AD 74) and Binnington Carr (AD 78). The more modern structures appear to coincide with the presence of the army.

As the years pass there are two more hoards which fit the pattern. A hoard of AD 98 comes from Mereclough in Lancashire at the southernmost edge of any hypothesized militarily occupied zone. It has an archaic structure. A second hoard of about the same date comes from Corbridge (AD 99): not surprisingly, because of the presence of the army, it has a modern structure.

So the pattern of modern hoards where the army was located, and relatively archaic hoards elsewhere appears to be true on the basis of the hoards from the north of Britain. Elsewhere, Usk (AD 57) has a hoard with a modern structure again quite happily relating to the presence of the army. Otherwise in the south-east most hoards are very similar. Could this lack of variation result from money circulating here fairly rapidly in this early period?

Map 2 Fig. 25.17 AD 100 - 149

There is a slight tendency for modern hoards to occur in the military areas. Six of the eight on Hadrian's Wall are modern, so are all the ones on the Antonine Wall. However, there are exceptions such as one of the Birdoswald hoards, which is fairly archaic. Surprisingly there is no sign of London as the provincial capital producing any great bias towards new coin around it; however, the data are fairly sparse. The picture here is generally slightly more blurred that in the earlier period.

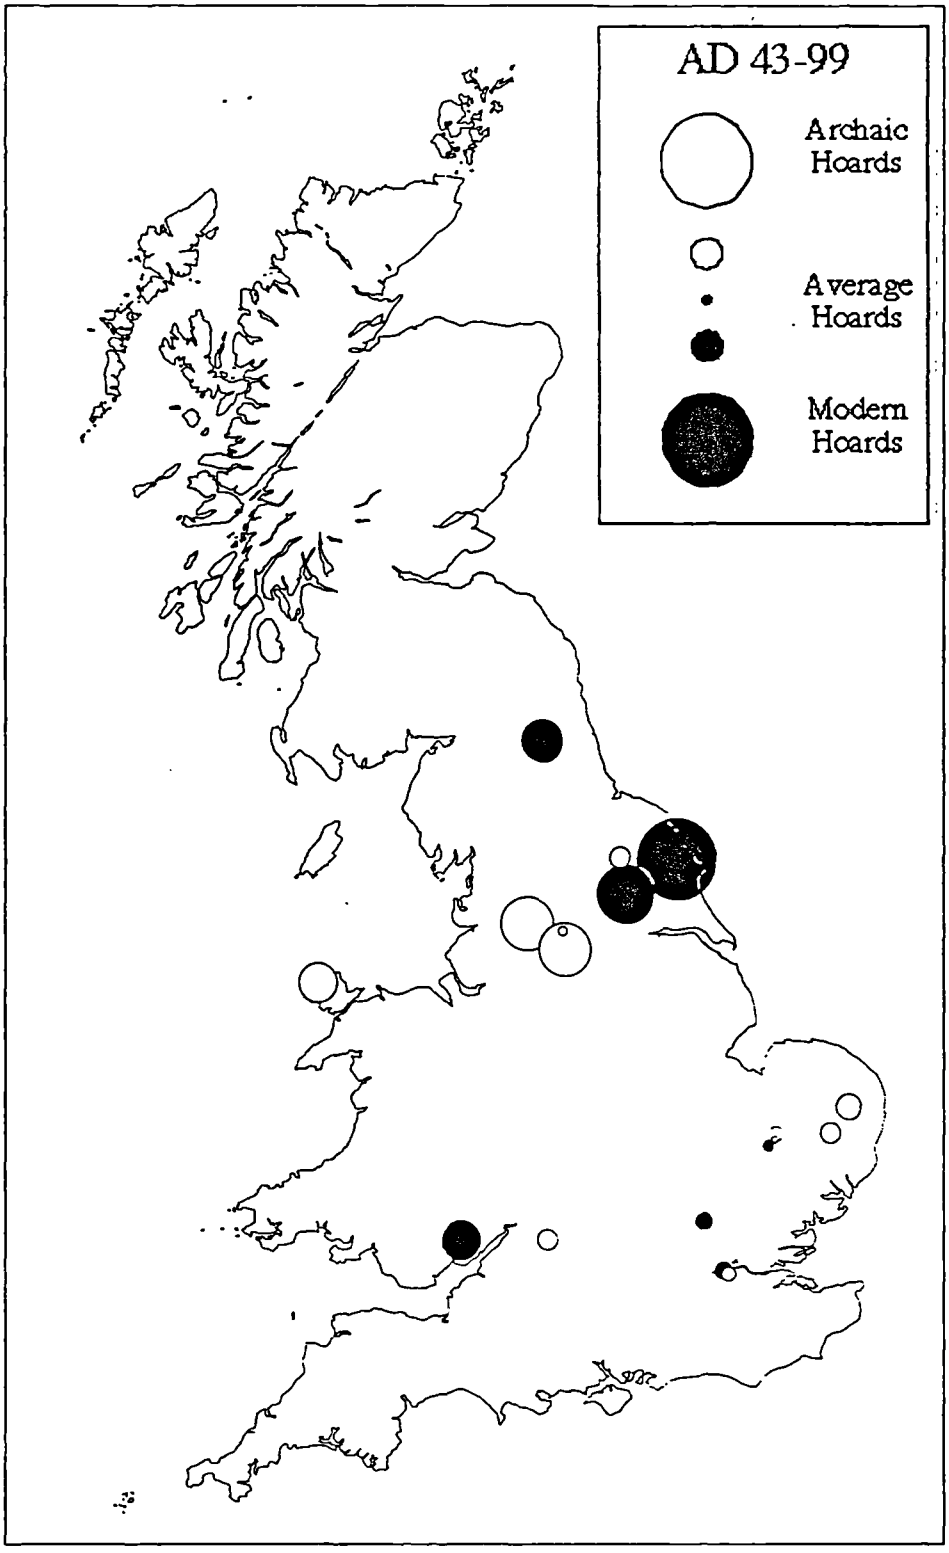

Fig. 25.16: The structure of hoards in Britain AD 43 - 99

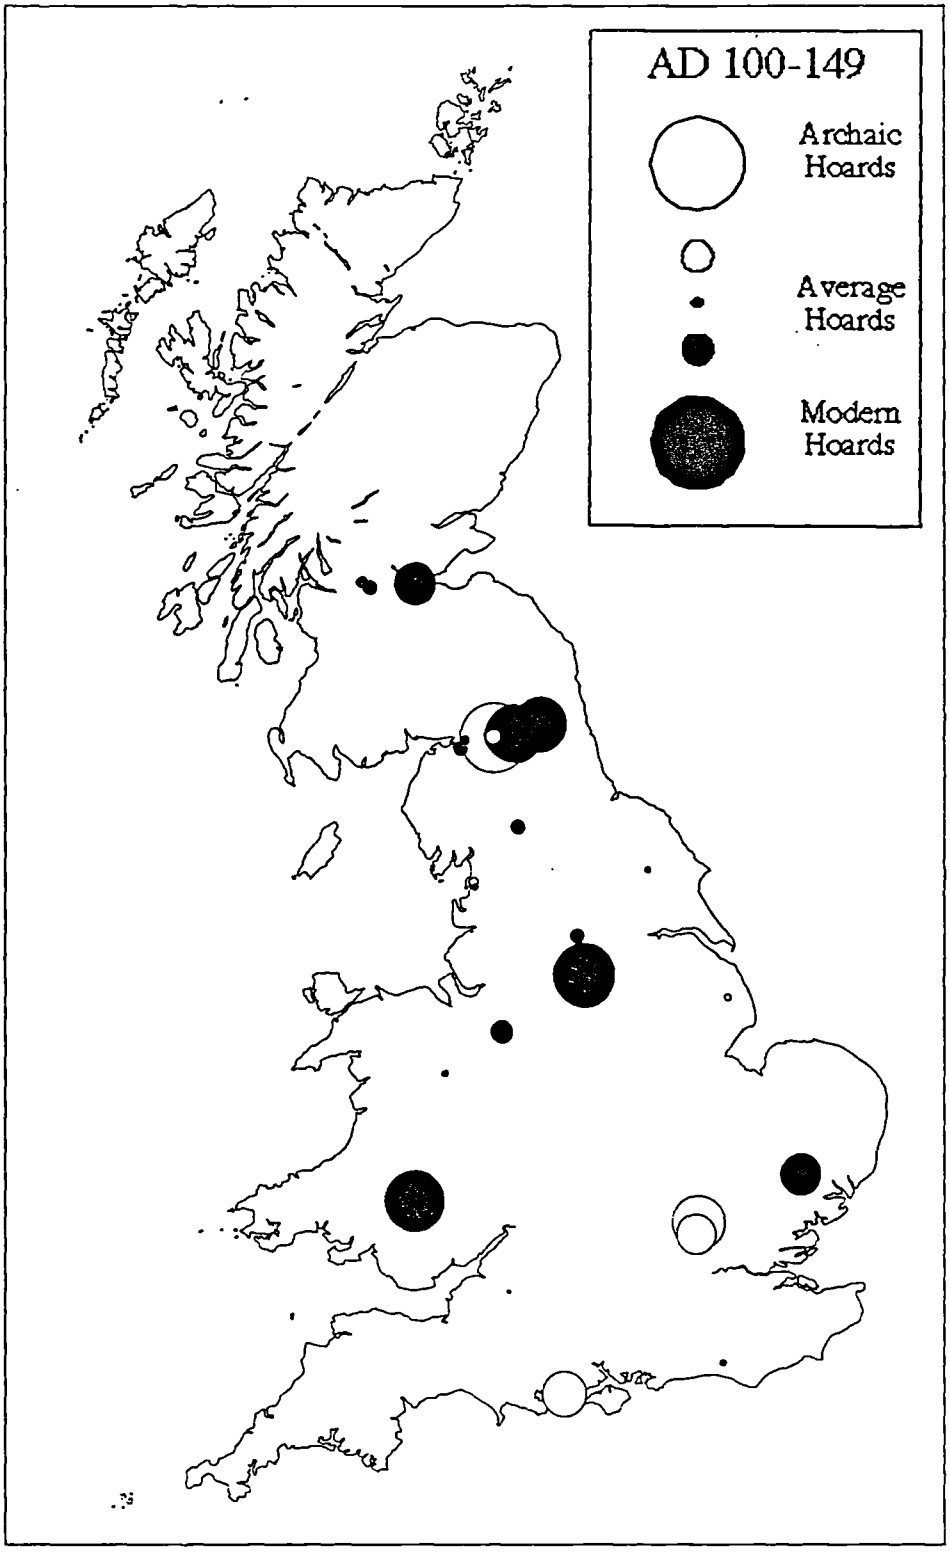

Fig. 25.17: The structure of hoards in Britain AD 100-149

Map 3 *Fig. 25.18* *AD 150 - 196*

In this period no systematic picture emerges. This period also coincides with the mid to late second century fast rate of circulation. It is possible that *denarii* are being exchanged so quickly across the province that any regional imbalances are disappearing very rapidly.

Map 4 *Fig. 25.19* *AD 196 - 238*

At this date we get a great slowing down in the rate of circulation of coinage with the massive Severan input of *denarii* . Therefore this is the date at which we would expect to see the most regional differentiation. Also by this time the province had been divided and the new border may have had restrictive effects on trade and the movement of coin. The picture we get is of a preponderance of new coin on the northern frontiers, and at Segontium. However, further north, in 'barbaricum' and south away from the army most of the assemblages are relatively archaic. The illustration again shows just how exceptional is the Falkirk hoard. London, however, still does not figure.

Map 5 *Fig. 25.20* *AD 238 +*

These are the hoards which contain *denarii* dating to after the coins replacement by the *antoninianus* , no particular patterning is to be found.

The maps do generally show that where the army was situated there tended to be more modern hoards. The difficulty in finding a pattern in the fastest circulation rate period of the mid to late second century does however seem to suggest that coins were moving around so quickly that no regional biases due to supply were sustained for very long. The conclusion that new coin entered circulation where the army was is not particularly startling, but it does place the generally held belief on a sound footing. What is more interesting is the absence of London showing itself on any of the maps. One might have expected new money to have come in to pay the provincial administration, but it appears that this was not the case. The simplest answer is that provincial administration was funded by taxation in the province itself, recycling the existing coin in circulation and passing some of the share on to the military. The military, on the other hand, may have had an entirely separate pay mechanism being paid centrally in new coin and taxes raised in a series of provinces rather than Britain alone.

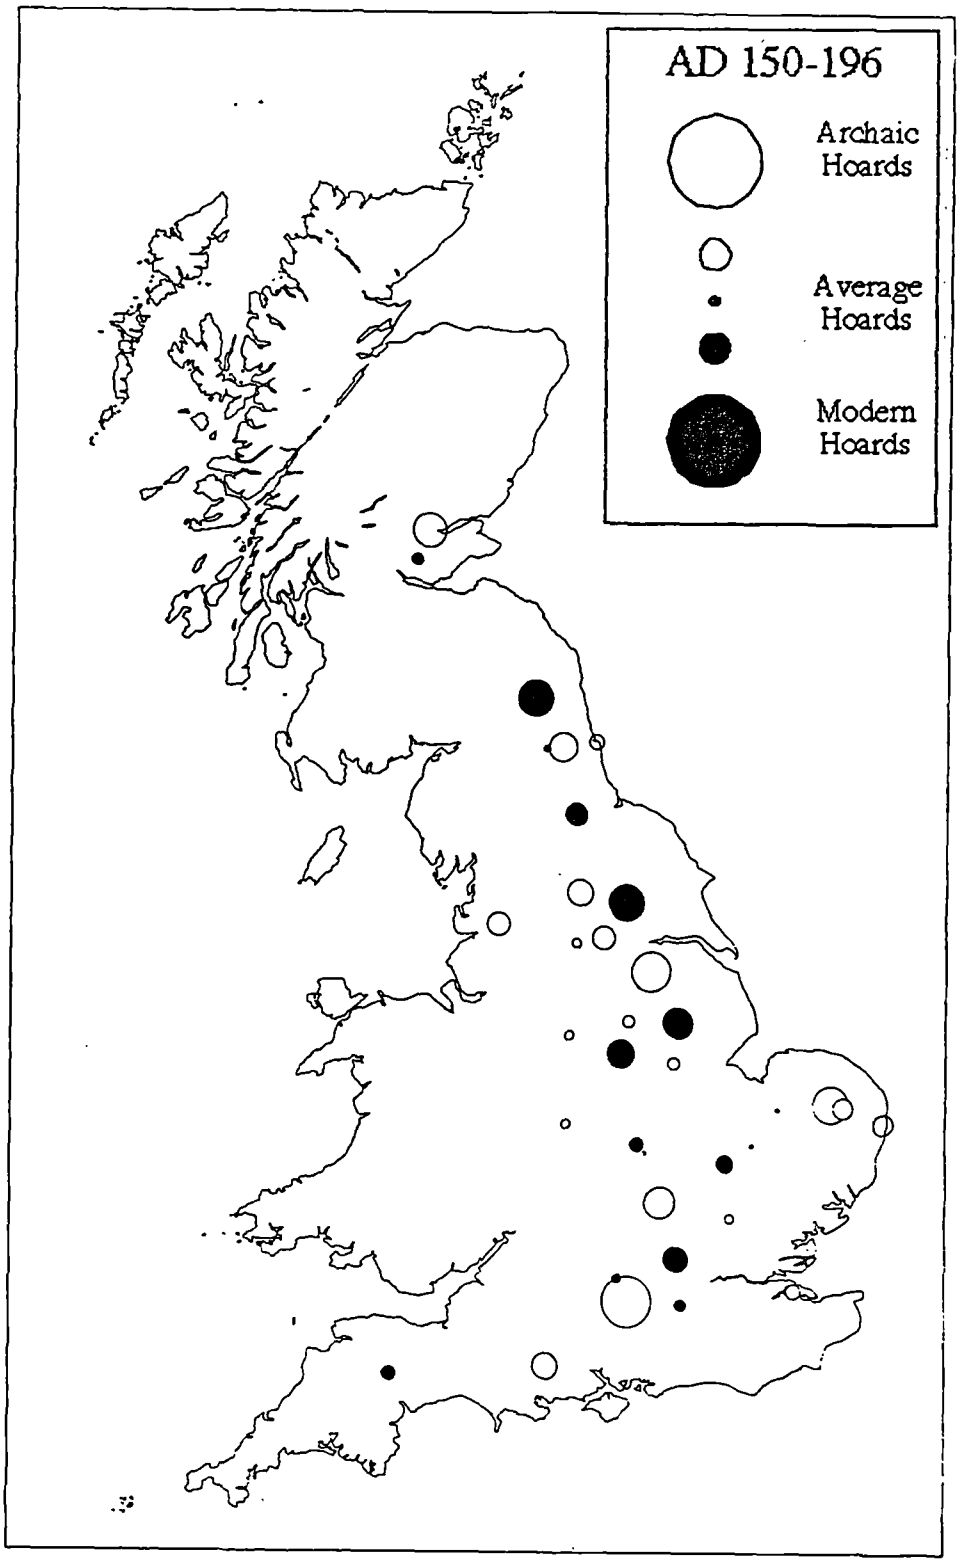

Fig. 25.18: The structure of hoards in Britain AD 150-196

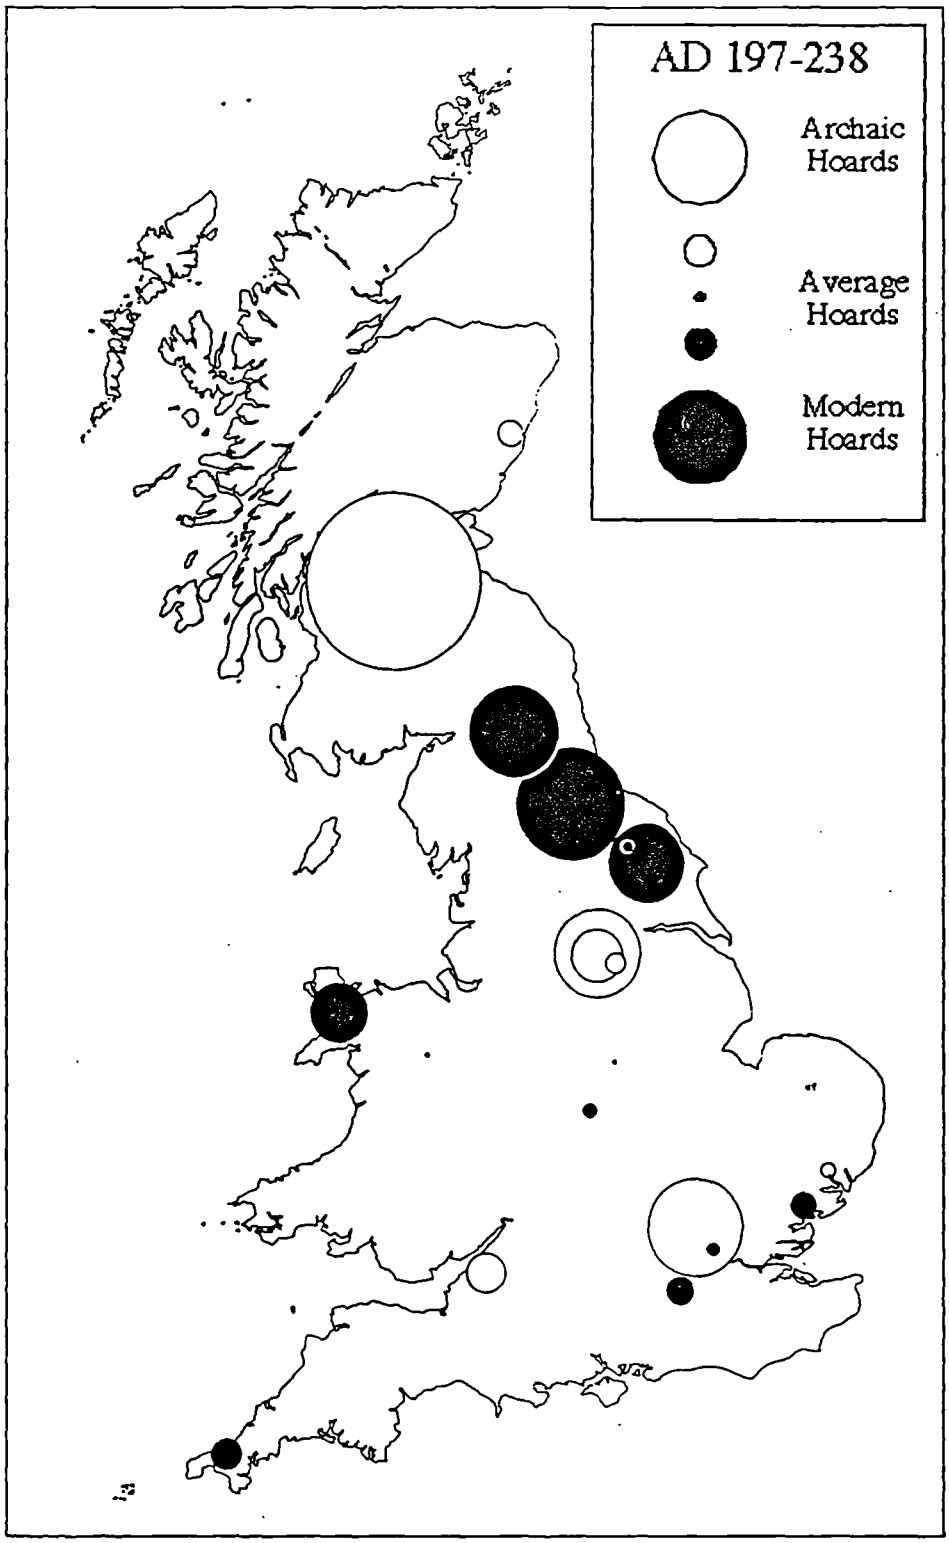

Fig. 25.19: The structure of hoards in Britain AD 197-238

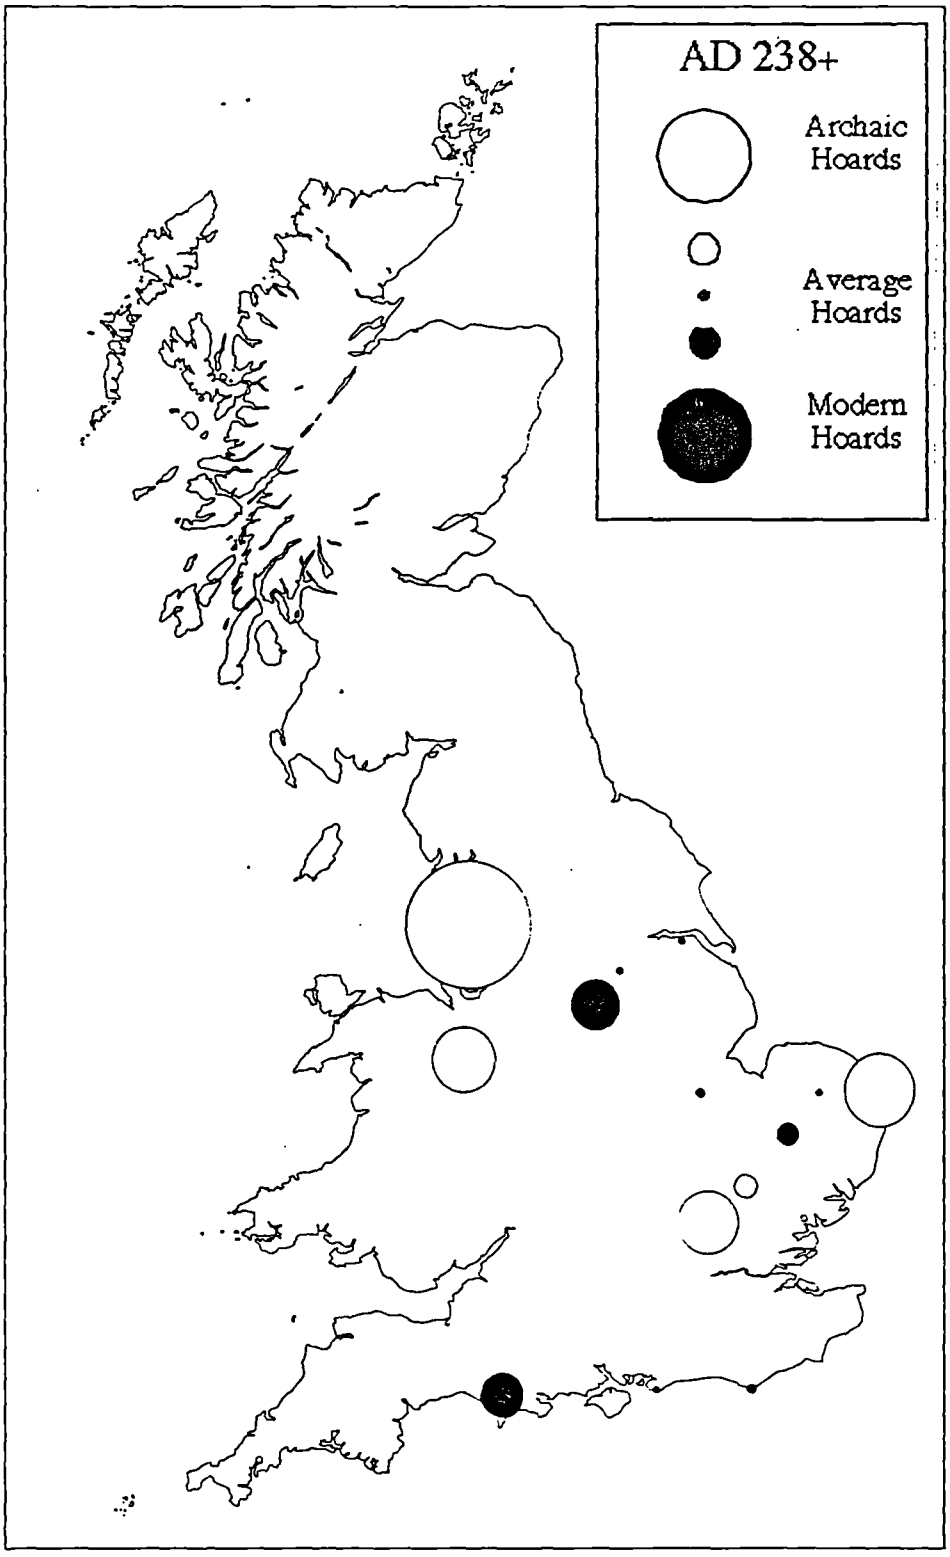

Fig. 25.20: The structure of hoards in Britain AD 238+

2.57 Conclusion

The methods of analysis outlined above are relatively simple once mechanised. The results concerning the velocity of circulation of *denarii* appear to correspond with the analysis based upon coin wear (Section 2.3). Great chronological variations can be seen in the variability of construction of coin hoards, and in their geographical distribution.

2.6 Hoard Size

This section looks at the information to be derived from the size of hoards Three main questions are asked. Is there any difference between the structure of large and small hoards ? (2.62) Is there any change in the relative numbers of big and small hoards through time? (2.63 & 2.64) And is there any geographical pattern to the distribution of abnormally large hoards in Britain? (2.65) But first the quality of the database is assessed (2.61).

2.61 The data

So far the internal structure of coin hoards has been examined without reference to their size. If hoards are selections of temporarily concealed and accidentally lost household money-boxes, then their size may contain a great deal of information on the amount of money that people were holding onto at any one time. Simple questions can be asked, for example: as the years passed on, did people store more and more money? Even if they had done so, this might not have reflected any real increase in 'wealth'. It is possible that a growth in hoard size might have been perfectly counterbalanced by a decline in the value of the coinage as a result of the debasement of the *denarius*. Secondly, if there was a growth in the size of hoards, was this an overall increase or did just the largest hoards get bigger, while the 'average hoard' remained the same size? The discovery of such patterns as this would have consequences regarding the changing social structure of Roman Britain. These are the kind of questions addressed in this section. However, first the database: we know the size of more hoards than those for which we have good structural information. Though not necessarily all those with good structural information can be used, since many comprise only segments of hoards whose original total size is unknown.

From our database, the number of hoards known to contain *denarii* is approximately 212. Of these only 160 have any reliable guide as to their size (let alone any further detail). Even here, some have no reliable details given of the latest coin in the collection. If we wish to analyse the size of *denarius* hoards, then we have only 156 to work with within the AD 40-280 period. Furthermore, if we wish to look at both size and structure, then we are further reduced to the 117 hoards which were included within our ancient and modern study.

2.62 Hoard size and hoard structure

Were larger hoards more archaic than smaller ones? The reason for this question lies in the possibility that hoards were static treasures slowly accumulated over many years, rather than dynamic money-boxes, to and from which money was constantly added and withdrawn. If the static model is correct then larger hoards should contain a higher proportion of older coin, their accumulation having begun at an earlier date. This idea can be tested by looking at a graph of hoard size against a scale representing the archaic or modern nature of hoards. Two such variables exist. Fig. 26.01 shows hoard size against the Net Area Deviation of each hoard compared with the 'normal' structure of its day. Fig. 26.02 uses the second method, measuring the antiquity or modernity of a hoard by the difference between its 'best fit' data and its actual *terminus post quem* . The pattern of both graphs is the same. Two trends can be found. First there is a broader scatter of the data above and below the line where smaller hoards are concerned. Secondly the smaller hoards do tend to appear slightly more modern in construction, and the larger hoard slightly more archaic. This second trend would tend to support the proposition that larger hoards tend to have been accumulated over a longer period. However, other reasons can be found to explain the pattern.

Here the effect that sample size has on the analysis must be taken into account. This all relates to the dating of hoards using a simple *terminus post quem* . To begin with the final coin in each group was taken to represent the date of closure of each hoard. If the coin could not be related to the issue of any one particular year but several, then the mid-point of its date range was taken to represent the date of deposition of the hoard. On the basis of this date the bench-mark of hoard composition through time was constructed (Section 2.42). Using the bench-mark the structure of each individual hoard was assessed. The composition of a hoard of one date was compared with the bench-mark, which gave an average picture for that time. The problem with this procedure is that the TPQ of a hoard might not have been its actual date of concealment; it only represents it earliest possible date of concealment.

In a large hoard the date of the final coin, the TPQ, is liable to be a fairly good indicator of the hoard's date of closure. In the case of a small hoard errors are more likely to occur. Because of the smaller sample size, there is more chance that such a hoard might not contain the latest issues in circulation. This would leave the hoard with an artificially early TPQ. The consequence of this is that in our structure analysis it would be compared against a falsely early date, showing it to have an erroneously modern structure. Hence one effect of sample size in our analysis would be to make small hoards appear slightly more modern than 'normal', and conversely larger hoards would

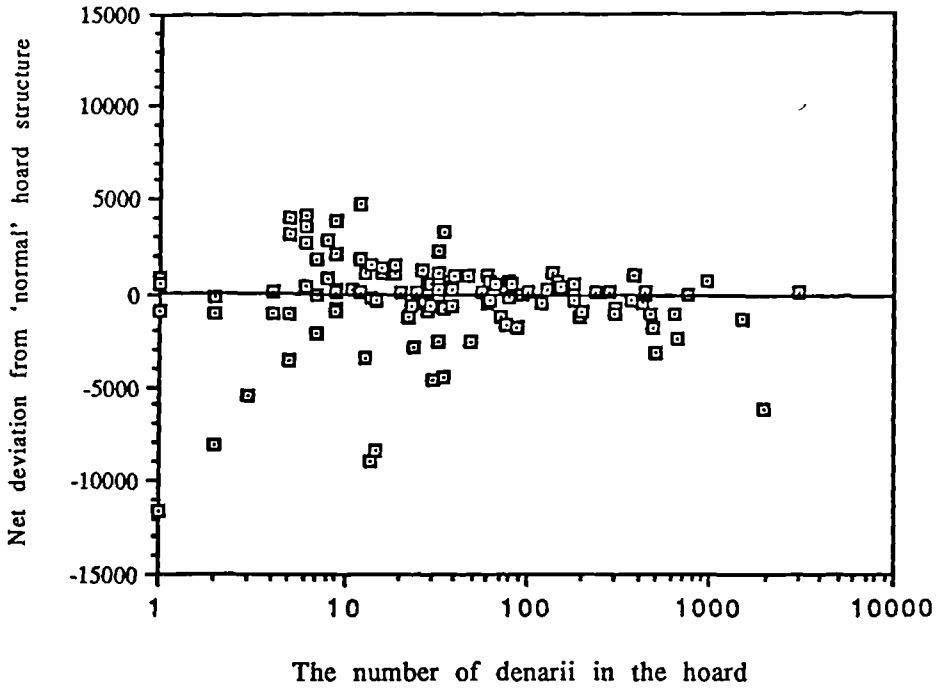

Fig. 26.01: Hoard size and hoard structure (using the Net Area Difference variable).

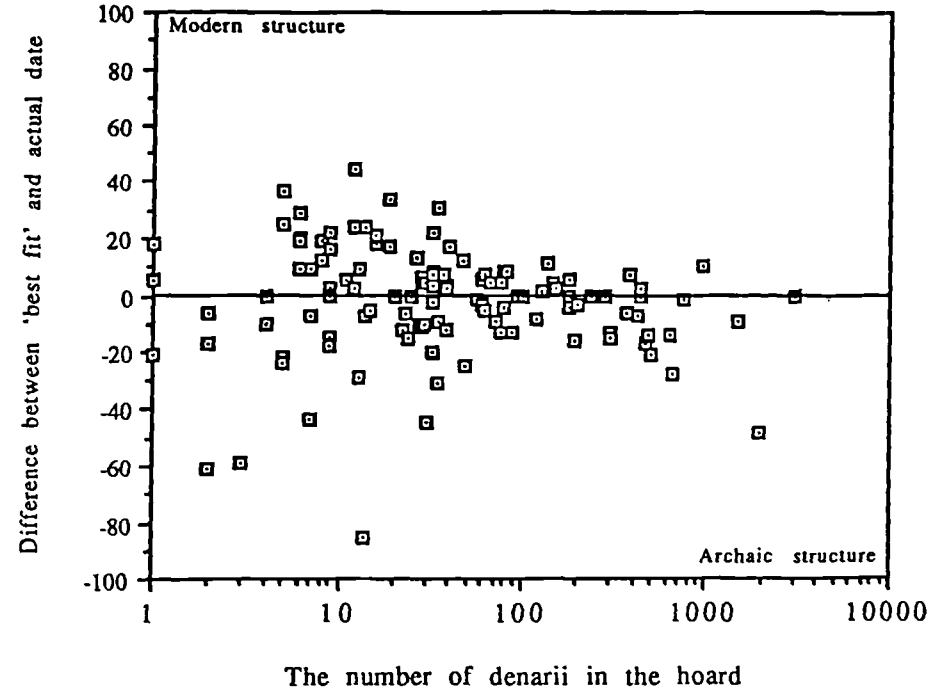

Fig. 26.02: Hoard size and hoard structure (using the 'best fit date' variable).

appear slightly more archaic. A second effect is simply that the cumulative composition curves of smaller hoards are going to be much coarser than those with larger samples; therefore smaller hoards will show a greater variation around the norm than larger ones, simply due to the lack of precision caused by the small sample size. Both these trends are those observed in figs. 26.01 and 26.02.

This trend for small hoards to appear modern, and larger hoards to appear relatively archaic is simply a symptom of the way hoards were dated in the analysis using a simple *terminus post quem*. It does not mean that larger hoards are more archaic because they have been accumulated over a longer period. There is no evidence for this proposition which cannot be explained by sampling error.

2.63 Hoard size and rank-order graphs

Now the size of hoards are examined in their own right. When all imitation coins and partial hoards have been removed we come down to the information displayed in fig. 26.03 (data in Appendix 2.61). The first impressions are of a gradual rise in the size of hoards throughout the first and second century, until the introduction of the *antoninianus* . At this date the number of *denarii* in hoards falls off. However, this is by no means the whole story. Though the size of the largest hoards certainly increases, there is still a strong undercurrent of hoards with less than 100 coins in them. What we have is not an average hoard size with a normal distribution around it, but more of a skewed distribution with lots of smaller hoards with only a tail of larger ones. Fig. 26.04 shows this by plotting the mean and median size of hoards. That the median is always well below the mean indicates that the average size of hoards is not a very meaningful variable. Even so, there does seem to be a gradual increase in *denarius* holdings, though this is only particularly noticeable at the end of the second century; just when there was a large Severan input of *denarii* into circulation.

For the moment, however, it is the changes in the distribution of *denarius* holdings that I wish to look at. The best way to examine this is to divide up the hoards into broad chronological groups. Here approximately fifty year periods have been used. Within these bands the hoards can be ordered by size to produce a rank-size graph. An example for the first half of the second century is given in fig. 26.05.

This kind of graph illustrates the equality or inequality of *denarius* holdings as recovered by coin hoards. The more concave the curve is, the more unequal the distribution of coinage is. By forming these graphs it is possible to test various ideas about changes which might have been taking place in Roman Britain at that time. Two such changes are the degree of social stratification in society and the level of

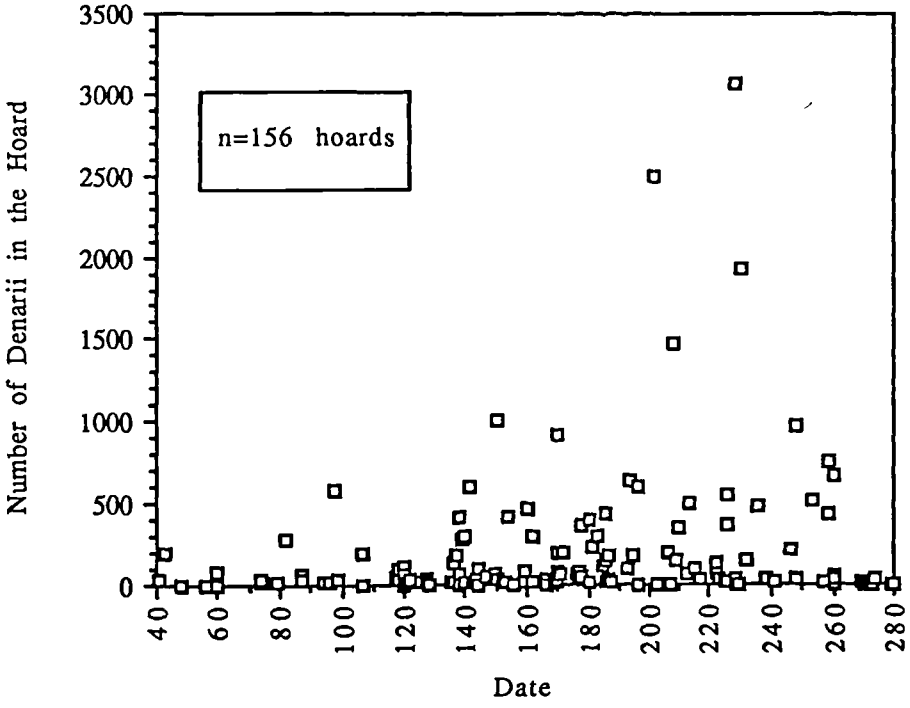

Fig. 26.03: The size of *denarius* hoards: AD 40-280.

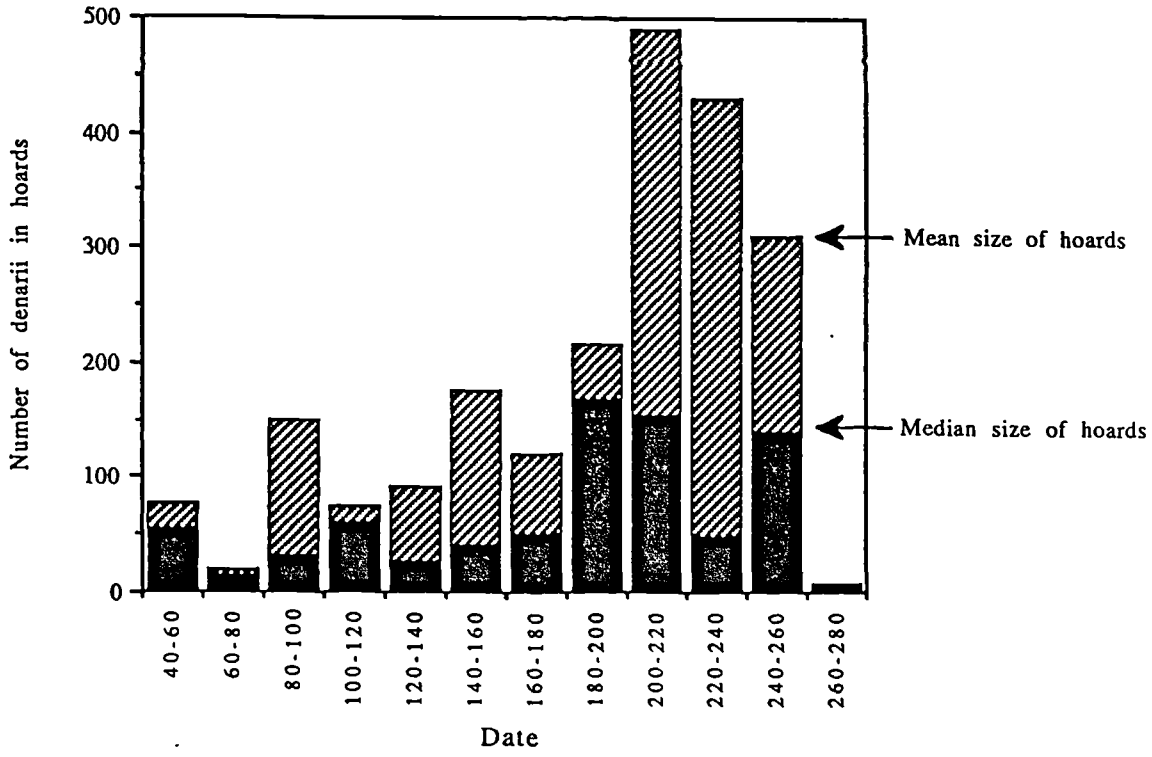

Fig. 26.04: Mean and median hoard size: AD 40-280.

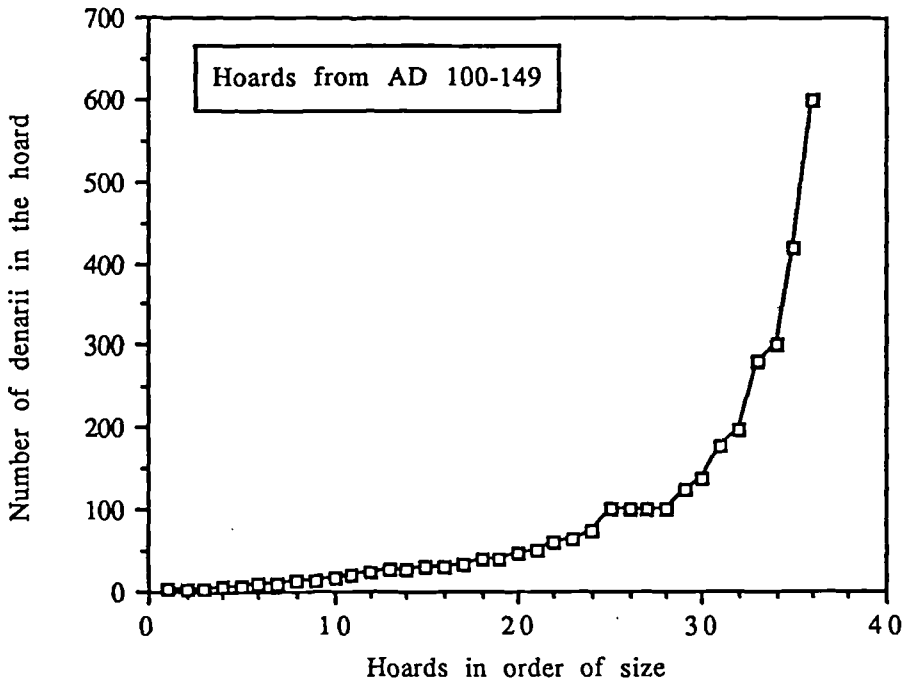

Fig. 26.05: Rank-size graph: hoards in AD 100-149.

monetization of society. How would we expect the idea of 'the rich getting richer' and 'the trickle down model' to manifest themselves in such a graph?

The rich getting richer:
If this were the case then we would expect that the larger hoards gradually got larger still relative to the smaller ones around at the time. This would have the effect of making the rank-size curve more concave (as explained in fig. 26.06).

The trickle-down model:
If the use of coinage slowly spread to more and more people, it would be fair to assume that novices to the monetary economy would enter it at the lower end, with small holdings. This means that relatively more people with small holdings would start to exist, also leading to a more concave rank-size curve (again explained in fig. 26.06).

The converse to both of these is also true. We would expect both a decrease in social stratification and a reduction in the participation of the monetary economy to reveal themselves in the trend towards a less concave curve. Both these variables (which ever way they operate) seem quite likely phenomena that might be expected in Roman Britain. What then are the results?

2.64 Results and interpretation

Fig. 26.07 shows the changes from the conquest to the early third century. The curves have been adjusted so that they can all be plotted on the same scale. 100 represents the size of the largest hoard in each period. In the first century the largest hoard contained 580 coins whereas in the later second - early third century the largest contained 3062 coins. By converting them all to a scale of 0 to 100 enables comparisons to be drawn. Similarly the horizontal axis has been adjusted to take account of the different number of hoards in each period. The result is one of virtually no change in the relative distribution of *denarius* holdings in the first to early third century at all. Over two hundred years roughly the same proportion of people have large hoards to those with smaller holdings.

There are two alternatives: either society in Roman Britain is totally stable, and monetization is reaching no more people in the early third century than it did in the first century; or else both 'trickle-down' and 'the rich getting richer' models are both in play, but in different directions.

The possibilities are as follows:

1. Totally stable social structure and no changes in the degree of monetization.

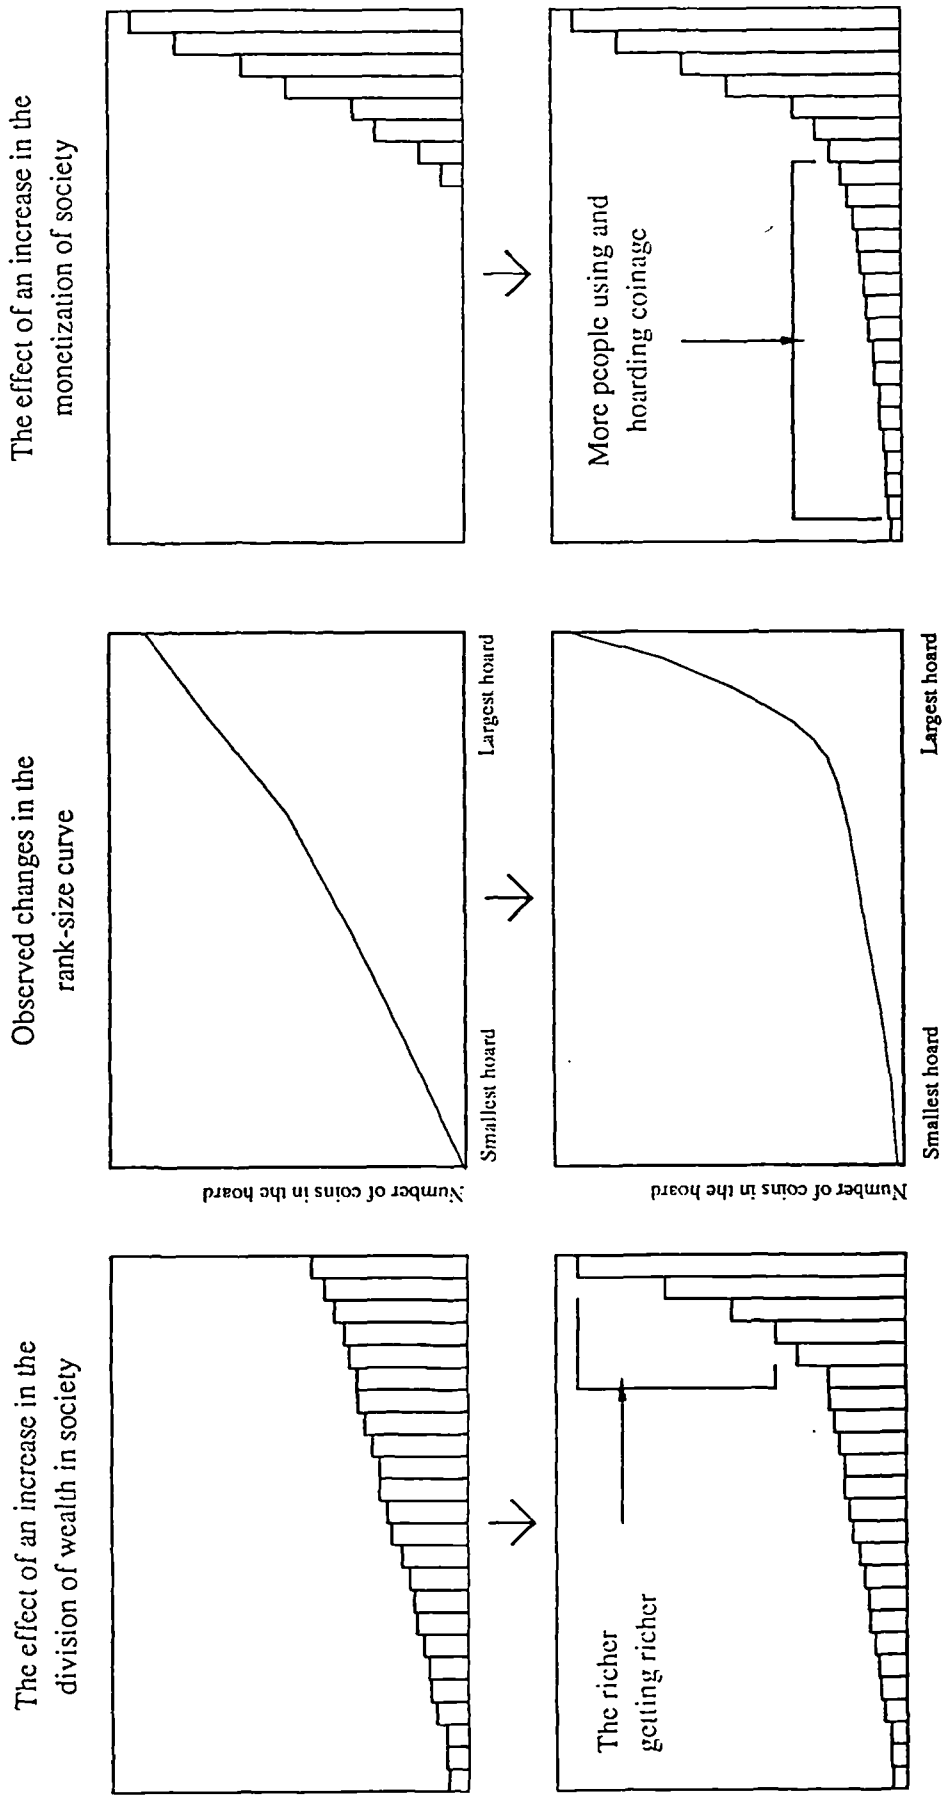

Fig. 26.06: Two models exploring the changes in an hoard rank-size graph.

2. The rich are getting richer (increased social stratification) leading to a concave curve; whilst there is a contraction of the number of people handling money, counteracting the concave effect of the former. However, it seems difficult to imagine an actual contraction in coin use during this period, so I find this alternative unlikely.

3. There is an increase in the number of people using coinage, but the effect on the curve is counteracted by a decrease in social stratification. The rich are by no means getting richer; rather the increase in monetization and other effects of the post conquest changes lead to a gradual breakdown of the pre-existing social divisions rather than a fossilizing and extension of them.

There is no definite way to decide between the options to explain the similarity of the rank-size curves. If one sees the growth in the degree of material culture in Roman Britain and the large number of coins found on sites (as well as the growth in the number of hoards) as all indicating a growth in some form of monetary economy; then it is difficult to accept either options one or two. We would have to envisage a decrease in social stratification going hand in hand with the monetization of the economy if we are to explain the stability of the shape of the curve. But is such a perfect balance between the two likely? I tend towards the notion of stability (Option 1), though as stated there is no definite way of distinguishing between the options.

It is possible to continue this analysis beyond the duration of the *denarius* into the lifetime of the *antoninianus* . The data are provided in Appendix 2.62. Here we do have differences in the shape of the curves. The first, from the decline of the *denarius* until AD 265 is much less concave than any of the earlier curves. The hoards in 276-85 show a similar distribution to the *denarii* , but those for 266-75 and 286-99 are more concave. The lack of single simple trend warns against any detailed interpretation from period to period. The nature of the collapse of the monetary system in the late third century might also distort the picture. I only wish to draw attention to one feature of the graph, that of the curve for the years up to AD 265. During this period coinage in Britain was in very short supply. The *denarius* had stopped being issued and *antoniniani* had not arrived in the country in any significant numbers (this is dealt with in section 4.4). If there was a shortage of coinage then we might expect a decrease in the level of monetization, as some people returned to alternative exchange mechanisms without using coins. This would be shown by a less concave curve, which is what appears. From the sole reign of Gallienus in the 260s this shortage was alleviated with vast numbers of debased coins; and a reversal to a more concave curve is found.

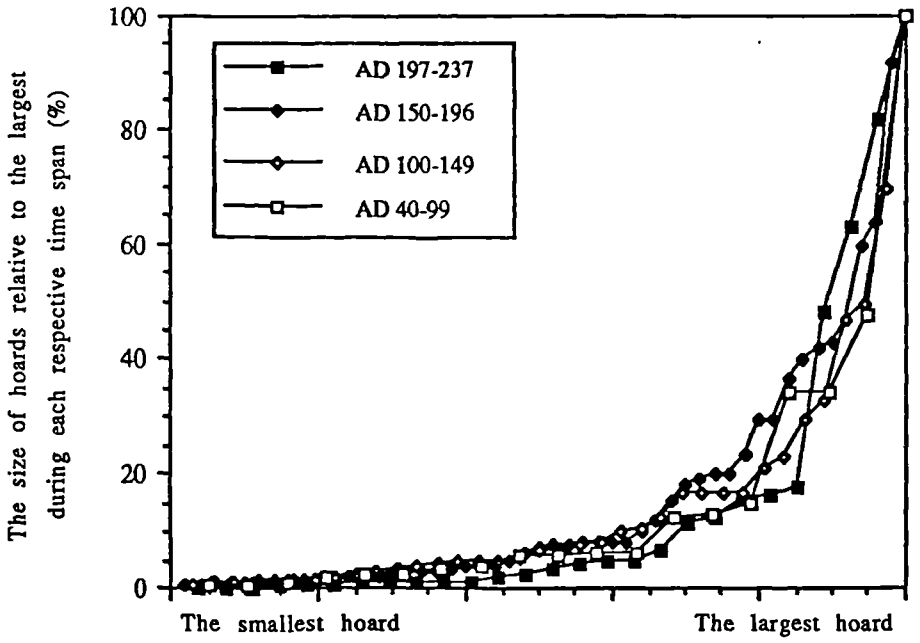

Fig. 26.07: Composite rank-size graph: *denarius* hoards in AD 40-300.

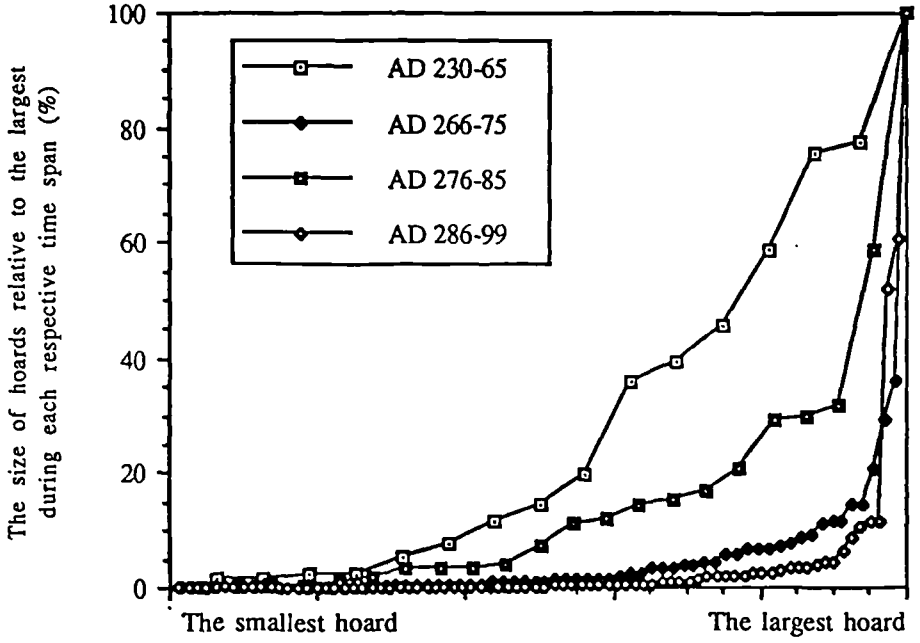

Fig. 26.08: Composite rank size graph: later third century hoards.

However, these events and the changes in the shape of the curve may be entirely fortuitous. This interpretation is highly subjective, but is offered nonetheless.

2.65 Where are the big hoards ?

In the preceding sections it has been assumed that the spread of differently sized hoards across the country was uniform. If all the large hoards were in the South of Britain, whilst all the smaller ones were in the North then analysing rank-size graphs for the country as a whole would be meaningless. This therefore needs to be examined.

The hoards in each of the period groups have been divided up into quartiles. The first quartile represent the smallest hoards, whilst the fourth represents the largest (Appendix 2.63). The country has been divided up into three regions.

Zone 1: The south east of England, where the most highly developed Iron Age monetary systems existed.

Zone 2: A band around Zone 1 where the less developed tribal coinages of the Corieltauvi, Iceni, Dobunni and Durotriges were spread.

Zone 3: The areas where there were no monetary systems established prior to the Roman conquest.

The relative proportion of hoards from each zone is shown in fig. 26.09, divided up by hoard size and chronological group. No consistent regional trends appear, except possibly in the first period (AD 43-99). Here all the hoards from Zone 1 are in the largest category (the 4th quartile). This might indicate more money was circulating in the areas which already had a developed monetary system established. However, as the trend is not repeated in the subsequent periods the conclusion must be highly tentative. Otherwise there is no evidence for any regional concentrations of the larger *denarius* hoards in Britain.

2.66 Conclusions

1. There are no structural differences between large and small hoards other than those which can be explained by sampling error.

2. There is a uniformity in the distribution of *denarius* holdings from the conquest to the introduction of the *antoninianus* . Either this reflects a tremendous degree of social stability in this period with no increase in the proportion of the population using money; or else an increase in the role of money in society is being matched

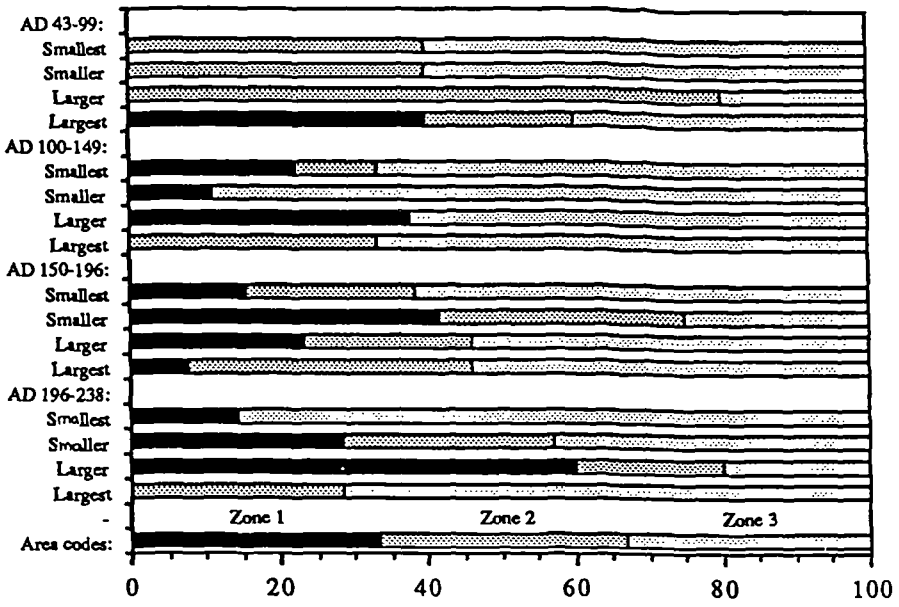

Fig. 26.09: The location of *denarius* hoards, divided up chronologically and by size.

by a decrease in the degree of social stratification. The data cannot distinguish between these possibilities, but the author prefers the former.

3. The shortage of coinage between the demise of the *denarius* in 238 and the large scale production of the *antoninianus* in the 260s might have resulted in a temporary decrease in the number of people operating within the monetary economy. However, this interpretation of the evidence is very tentative.

4. The only regional pattern to be found in the distribution of different hoard sizes is that all the hoards in the more highly developed South-East of the country in AD 43-99, were in the largest size range analysed. This might indicate more money being in circulation in this region in the period than elsewhere as a function of the replacement of the Iron Age currency by Roman coins. However, the pattern is not sustained beyond AD 100. The conclusion is again tentative.

Section 3: Site Finds and the Circulation Pool

3.1 Historical and Conceptual Survey

This chapter examines the ways numismatists have used the evidence of site finds. It then investigates the variables which have been taken to determine how and why coins are lost and not recovered.

3.2 Site find database

In this section the site find database is discussed, its origins (3.21), its extension (3.22) and its structure (3.23).

3.3 Site find analysis

In this section the differential deposition of coin on different types of site is examined. Interpretations are made relating the nature of deposition to the integration of sites within the monetary economy. However, the study is essentially a traditional analysis based upon the static view of coin circulation (fig. 31.01). The limitations and problems of such an analysis are discussed and the need for a more dynamic model of circulation dynamics is called for.

3.4 A new model of coin circulation

In this section we explore various concrete suggestions made to tackle the problem of residuality. These include Muller's, Collis', and Crummy and Terry's models (Muller 1968; Collis 1974; Crummy and Terry 1979). An entirely new model of circulation dynamics is called for, one which uses evidence and data that is already available and one which fulfils the criteria that it can be tested and validated or nullified. One is then created: first expressed in words and ideas, then in mathematical terms and expressions.

3.5 Testing the model

In order to use the model for the analysis of *denarii* in Britain we need the following information. First a representative sample of *denarii* deposited on British sites needs to be established (3.51). Secondly metrological and metallurgical details are required to establish a preferential recovery factor (3.52). Thirdly a routine for generating the model has to be established (3.53). And finally the results have to be compared with extant knowledge and tested to see if they bear any relation to reality (3.54 -59).

3.1 Historical and Conceptual Survey

This chapter examines the ways numismatists have used the evidence of site finds. It then investigates the variables which have been taken to determine how and why coins are lost and not recovered.

3.11 Introduction

In many ways hoards and site finds are complimentary. Hoards often contain the higher value coins in circulation, whereas site lists are dominated by the smaller denominations. Nonetheless there is some overlap. This is especially so in the fourth century, where the rapidly changing billon and bronze coinage can be found both in hoards and as site finds in large numbers. Conversely, *siliquae* , best known from hoards, are rare as stray losses.

Site finds, as a phenomenon, are deposited by the action of a different set of factors to those governing hoard accumulation and loss. Here we have a different set of processes at work on our 'circulation pool', and this means that there might be a second way of modelling back to our original coin population. If so, we need to have a thorough understanding of how coins are lost and why they are not recovered.

3.12 Previous studies of site lists

In his study in 1935, O'Neil explicitly divided 'site lists' from other categories of numismatic data. He separated them from isolated stray finds and individual excavation lists, as well as from hoards. He examined a group of site lists comprising Silchester, Wroxeter, Caerwent and Verulamium. Each list was converted into a percentage break down of various coin periods. Then comparisons were made between the sites. As we would now expect, consistencies were found in the variations in the chronological proportions of coins found on the sites. Thus O'Neil pointed out that these major variations in the numbers of coins found on sites in different periods was not a function of differential levels of occupation, but rather a function of supply.

Over the years, O'Neil's simple coin periods for analysing Romano-British site finds have become elaborated and extended. Casey and Reece have both devised series of coin periods which have become a fairly standard way of dividing up the data, and Haselgrove has extended them back into the Iron Age period for Celtic coinage (1987).

The division of the data into percentages has also seen a number of changes. While the method is straightforward, simple histograms with the data did not take into account the differing lengths of each coin period. To counter this, Ravetz (1964) added a correcting factor by dividing the number of coins in each period by the length of the period. This method, used first on fourth century coins, has since been extended to become, like the coin periods above, a standard way of visually summarizing site find data (Casey 1974, 41).

The equation used is: $$\frac{\text{Coins per coin period}}{\text{Length of coin period}} \times \frac{1000}{\text{SITE TOTAL}}$$

So far this is all a logical extension of O'Neil's first steps. The '1000/Total', like the conversion into percentages, standardizes the data from different sized site lists, and the rest simply creates a good visual illustration of how many coins were being lost on the site, and of which date.

O'Neil, as stated, looked at four town sites, and believed he saw a background picture of 'coin-supply'. Any comparison of a group of 'coins per thousand' histograms will confirm that there are indeed great similarities between different sites (cf. Casey 1986, 91-94). Reece took the next logical move to quantify variation from this background level (Reece, 1983). He took a number of site lists and averaged them to create what could be taken to represent a 'normal' site. The variation of the sites in each coin period was expressed as a standard deviation. Individual sites (Lincoln in this case) could then be compared against this data. Deviations greater that one standard deviation could be noted as significant, representing marked changes in the supply/use of coin on the site to what one might expect. Reece's method is not without its mathematical problems (Reece 1988a, 22). Also systematic trends frequently emerged which were of an order of magnitude less than one standard deviation, so technically they were not 'significant'. Finally the use of standard deviation assumed a normal distribution in the coin population, an idea which was not proven. Nonetheless since systematic trends did emerge, on a purely pragmatic basis, this method was useful.

The methodology above, though developed for coinage, can and has been used for other types of material culture. The 'coins per thousand' approach was used on brooches by Brown (1986), and this technique was then extended in a similar manner to Reece's analysis of variance by Creighton (1990).

The whole series of models form a continuum of developing theory and ideas. Nonetheless, at their foundation is a problem which nearly all numismatists would

admit to: the model is static. The histograms only convey what was lost, they do not tell us when that loss took place. As Casey says:

> "We have already seen that individual coins can have long lives, up to several centuries in some cases, and to this extent confining the study of coins to the display format of the histogram does some violence to the evidence. The very rigidity of the boundaries of the visual display is an illusion because it fails to show the way that coins of each defined period are present in the currency of any later period. We must face the problem of how to establish how long a coin might be in circulation before becoming incorporated in an archaeological context."
>
> (Casey 1986, 105)

Another criticism would be that the graphs rarely present a visual image of the types of denominations lost. No distinction is made between the loss of a *denarius* and the loss of an *as* ; and yet in terms of economic reconstruction, surely this information must be taken into account. This is not to say that the histograms are of no worth, far from it. It is merely to state that if we are trying to reconstruct a pattern of the money supply, then we cannot start from this junction, based as it is on a static image of circulation dynamics.

Haselgrove (1987, 37) illustrated the differences between the static and dynamic images, redrawn here as fig. 31.01. When there was a regular recall of the coinage, as in Anglo-Saxon England, the static model has a good approximation to reality. However, in a system where Republican *denarii* were still circulating in the second century AD, the longevity of coin circulation must be taken into account. Casey's coin periods for Roman Britain start with Claudius in Period 1 (AD 43-54) (Casey 1974, 43); despite the fact that in Claudian to Domitianic hoards, coins of the Republic and Mark Antony often account for well over half of the *denarii* present (cf. Reece 1974, 83). The problem of longevity cannot be ignored. It needs to be tackled. Haselgrove's illustration was largely derived from Collis (1974), where a larger set of illustrations were presented looking like schools of hump-backed whales. They represented the growth in the volume of coinage as a coin series entered circulation, and its slow tailing off, as it was either unsystematically recalled or was lost. Reece went some way to demonstrating this type of curve for the *denarii* of Antoninus Pius in hoards from 138 to 268 (Reece 1974, 83).

3.13 Variables effecting coin loss

With this idea of a dynamic system in mind, somehow coins were lost. Here we are talking specifically about accidental loss and non-recovery, not votive deposits. Site lists at 'temple sites' or from votive wells such as Coventina's Well cannot be examined in the same category, as here discard was deliberate and premeditated (cf. Casey 1989).

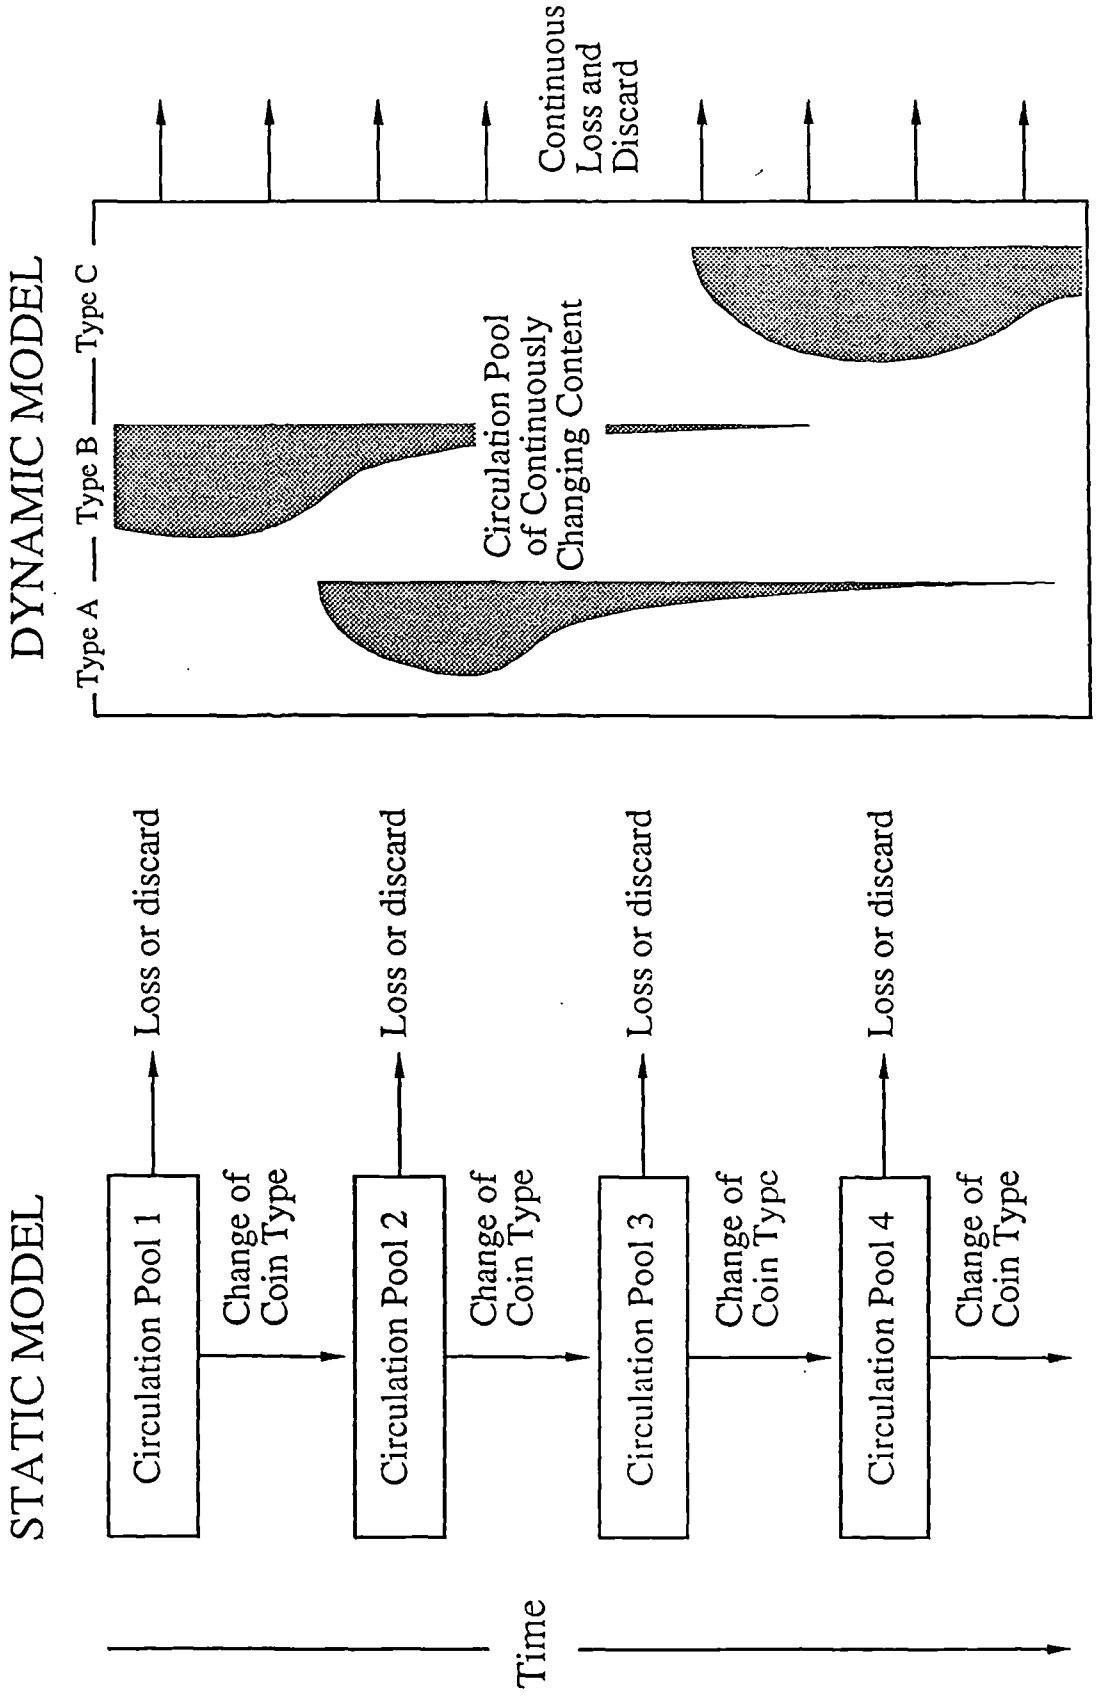

Fig. 31.01: The static and dynamic models of coin circulation (after Haselgrove 1987)

Casey (1986, 69) identified 5 variables effecting coin loss:

1. The size of the issue
2. The intrinsic and relative value of the coin
3. The size of the coin
4. Political factors
5. Economic factors

The first, 'size of issue', is straight forward. The more coins of one type in circulation the greater the chance of one being lost. So all other things being equal, loss is proportional to the size of issue.

The second factor is also straightforward, though not so easy to quantify. We have already noted the truism that site finds generally consist of a larger proportion of low value denominations than hoards. This can partly be put down to differential retrieval factors. More time would be spent looking for a lost *aureus* than for a dropped *semis* . One could imagine that loss is approximately inversely proportional to value, however, though this relationship seems to be one of common sense, it relies on an assumption about human actions. A complicating factor would be the changing value of coins. *Sestertii* in the first century AD may have been worth more than their successors in the third unless they maintained their value against the declining 'silver' *denarii* and *antoniniani.*

The third variable is similar to the second, in that the larger a coin, the more likely it is going to be seen and retrieved. Also, the less likely it is going to be lost through a hole in the pocket, purse or whatever in the first place. One could therefore suggest that loss is inversely proportional to coin size; but again this is untested, though with common sense (for what it is worth) behind it. The colour of the metal would also have an effect. A silver coin showing up better in the mud than a bronze coin. On the other hand, as fieldwalkers and farmers will know, a circular object on the ground in the soil, has a way of standing out to the eye from quite a distance, because of its regular geometric form, whatever the colour.

The fourth factor is 'political'. The main way that this affects us is in the Roman practise of *damnatio memoriae* :

> "The concept of 'damnatio memoriae' was reserved in Roman law for the extinction of the memory of those whom, in their lifetime, the state had been unable to control. This effectively meant emperors whose actions were more than usually inimical to the interests of the senatorial order, but whom these same senators had treated with awed deference in their lifetime. The list of emperors subjected to *damnatio* is long... We know that the coinage of Caligula was melted down, as was that of Geta, the brother of Caracalla."
> (Casey 1986, 29-30)

This may result in either too few coins being lost, as their life-span in circulation would have been curtailed, leaving a shorter period over which they had to be lost in; or it may result in more coins being lost, as people discarded politically unacceptable coins. No simple relationship between coin loss and 'political factors' can be created here.

The fifth factor is the economic situation. This again may have particular effects when coinage reforms take place and earlier issues are demonetized. Here pre-reform coins may appear to be lost in greater quantities than expected due to the discard of demonetized issues; or conversely in smaller quantities because the reform would have prematurely removed them from circulation as above. Again no simple relationship can be established.

One factor which Casey does not relate here is the length of time for which a coin was in circulation. If we add together three descriptives: 'the number of coins in circulation', 'the longevity of circulation' and 'the denomination and metrology of the coin', then we have a triad which can explain a lot of the variation in coin loss.

Coin loss triad:

1. Loss is proportional to the size of the issue in circulation at any time
2. Loss is proportional to the longevity of circulation
3. Retrieval is related to the denomination and metrology of the coin.

The withdrawal of coinage after a 'damnatio memoriae' or a coinage reform would be catered for by the effect on variables one and two. Both values would be restricted, so the subsequent number of coins of that series lost would be reduced. The main factor which this would not take into account would be the deliberate discard of redundant coin. This was a particularly important factor in the fourth century, though not so during the more stable period of the Augustan system until its collapse in the late third century. Variable three has been left fairly vague, underlining that it is difficult to make comparisons between different denominations. Nonetheless, the retrieval factor will be returned to at a later stage.

3.14 The alternative view of coin loss

There is, however, a rather different view of how and why coins are lost which has some currency at the moment. The differences between the standard view expressed above, and the following view have not yet been made explicit, nor have its implications been thoroughly explored. The alternative model has been proposed in the writings of Reece (1984; 1987, 30); these have been accepted in some quarters without the assumptions behind them being critically examined.

The basic tenet of the view is that "...on Roman sites, most coin finds may reasonably be regarded as losses from use..." (Haselgrove 1987, 36). This seems to have the great benefit of common sense behind it. It also contains implications of great advantage to the economic historian: if coin losses accurately reflect those coins which were exchanged most often, there exists the potential to reconstruct patterns of monetary inflation from changing patterns of denominational loss. But is this idea correct? Reece expressed the idea most clearly:

> "On a modern market stall nearly every purchase involves a pound coin going in one direction, safely into the till, and a handful of small change being returned; if any coin is dropped it is likely to be part of the small change and the chances of it remaining lost are directly related to its value."
>
> (Reece 1987, 30)

This suggests two primary factors determining loss: the number of exchanges a particular type of coin takes part in (the more exchanges, the greater the chance of loss), and the retrieval factor mentioned earlier. If we account for the retrieval factor, then we should be able to get back to the rates of exchange of the different denominations in the market place.

> "If the denarius is worth 64 times the value of the quadrans, and losses depend mainly on the number of times coins change hands and the value of the coin, then for denarii and quadrantes to be found in equal numbers denarii will have to change hands 64 times as often as quadrantes. But they are not found in equal numbers, there are ten denarii to each quadrans, so the denarii have changed hands 640 times the rate of quadrantes. This state of affairs can only have happened if there was a very large quantity of silver coin compared to the tiny amount of very small change."
>
> (Reece 1987, 31)

If this is the case with *denarii* and *quadrantes* , then what is the situation like with the full range of denominations? To examine this, it would be worthwhile to look at a series of site lists from near the heartland of the empire, in a period where some actual prices are known. The area chosen has been Italy in the mid first century AD.

Let us use Reece's own data from a series of sites in Northern Italy (Reece 1973). Here Reece's lists are divided into four groups: AR (*denarii* , and possibly a few *quinarii*); AE1 (*sestertii*); AE2 (*dupondii* and *asses*) and AE3 (*semisses* and *quadrantes*). The data are as follows:

Table 3.11: Site finds from Northern Italy in periods 1 and 2a

Period 2a (AD41-54)	42	114	469	151
Period 2b (AD54-69)	332	374	542	107
Period 3 (AD69-96)	1263	590	1688	142
Total:	2240	1506	4549	668

Table 3.14: Site finds from North Italy; table 3.13 expressed in percentages.

	AR	AE1	AE2	AE3/4
Period 1 (up to AD41)	19.2%	13.6%	58.7%	8.5%
Period 2a (AD41-54)	5.4%	14.7%	60.4%	19.5%
Period 2b (AD54-69)	24.5%	27.6%	40.0%	7.9%
Period 3 (AD69-96)	34.3%	16.0%	45.8%	3.9%
Total:	25.0%	16.8%	50.8%	7.4%

Each *denarius* was worth worth 16 asses ; so let us give 'AR' in our retrieval factor a value of 16. 'AE1' consists of *sestertii* , worth 4 *asses* . 'AE2' consist of *dupondii* (2 *asses*) and *asses* , so let us call this class 1.5 *asses* . 'AE3/4' consists of fractions, largely *semisses* and a few *quadrantes* , so let us call it 0.4 *asses* . If we multiply each by its retrieval factor, we will get to a relative breakdown of how many coins of each denomination were originally lost in each period.

Table 3.15: Modified number of coins originally lost in Northern Italy.

	AR	AE1	AE2	AE3/4
Period 1 (up to AD41)	9648	1712	2775	107

Period 3 (AD69-96)	20208	2360	2532	56
Total:	35840	6024	6823	267

Table 3.16: Modified no. of coins originally lost in Northern Italy (as a percentage).

	AR	AE1	AE2	AE3/4
Period 1 (up to AD41)	67.7%	12.0%	19.5%	0.8%
Period 2a (AD41-54)	35.5%	24.1%	37.2%	3.2%
Period 2b (AD54-69)	69.3%	19.5%	10.6%	0.6%
Period 3 (AD69-96)	80.3%	9.4%	10.1%	0.2%
Total:	73.2%	12.3%	13.9%	0.6%

According to Reece's idea, this would mean that about 73% of the coins exchanged were silver *denarii* . This figure seems remarkably high, unless we are willing to see the modal transaction value as being particularly expensive which goes contra to the evidence of graffiti from sites such as Pompeii. If the average transaction was less than one *denarius*, then we would expect smaller denominations to be dropped just as often; since there would be at least one 'bronze' coin given in change, if not more.

I do not accept this model of coin deposition, but let us examine some other evidence first. Burnett (1987, 118) referred to a judgement by Hadrian referring to market exchange taking place in Pergamum. There are a number of problems surrounding this inscription, but one thing it does make clear is that the medium of the market stall was

bronze coin. The prices of fish were marked in terms of bronze, and in the unusual case of a *denarius* being offered, less preferential rates of fishes per *as* came into play because the market-holder would have to exchange the coin at a money-changer's who would take a commission. In this case the idea of a modal transaction above the value of a *denarius* cannot be sustained. A second point would be that if *denarii* accounted for 70% of coin exchanges, why is it a commonplace that lower denomination coins are usually more worn than higher ones? Surely this model has to be mistaken.

This idea does not seem to work, there seem to be far too many *denarii* being lost compared with the number we would expect. If loss is proportional to the number of exchanges of a coin, then that loss must be taking place at the moment of exchange. Yet this is surely the moment when the coin is being closest observed, with two people's eyes fixed on it, and therefore loss - or rather non-recovery - would be far less likely. What then can account for the over presence of *denarii* ? One possibility would be that loss is much more of a random process than it is given credit for. Retrieval factors can only come into play when the loss has been noticed; and they are only going to become effective when the approximate location of the loss is known.

In the present day market place, people carry with them some small value coinage and larger notes, as well as a method of access to much larger sums of money: a cheque book or a credit card. In the ancient market place, the main medium was coin. Access to larger sums of money, should they be needed, could only be obtained by carrying higher value coinage. If loss acts randomly upon what a person is carrying then this hypothesis would give us our apparent over-representation of *denarii.* However, it is a difficult idea to test. One way would be to examine the coinage found on people buried in Pompeii.

The problem with the Pompeii evidence is the ever present possibility that the money found on a person might be an *armarium* being unsuccessfully rescued from the ensuing disaster. This must be born in mind and there is no easy way round the problem. However, 'hoards' do not often contain great mixtures of denominations. So if we find a mixed group of coins in a purse on a body we may have the evidence we are after.

Table 3.17: Mixed denominational 'hoards' from Pompeii; after Bolin (1958, 81):

[1] 1936, by a skeleton in amphitheatre:	Silver	131	(82.9%)	'Bronze'	27	(17.1%)
[2] 1879, by a skeleton:	Silver	36	(54.5%)	'Bronze'	30	(45.5%)
[3] c.1879, near to the above skeleton:	Silver	38	(97.4%)	'Bronze'	1	(02.6%)
[4] Sept 1908, in a purse:	Silver	46	(73.0%)	'Bronze'	17	(27.0%)
[5] Museo Nazionale 113076-113124	Silver	101	(-)	'Bronze'	+	(-)
[6] Museo Nazionale 124730	Silver	130	(70.6%)	'Bronze'	54	(29.4%)
Total (excluding no.5):	Silver	381	(74.7%)	'Bronze'	129	(25.3%)

The first three groups are all found near skeletons, and the fourth comes from a purse hoard. The last two are also included as they are mixed groups of coin of a similar size to the first, though their exact provenance is insecure.

These date to AD79, and were made up of a mixture of coinage dating back to the Republic. It is therefore legitimate to compare their composition to the aggregate picture of Italian town coin loss provided by Reece's data above. The towns gave an impression of 25.0% of the coins lost being *denarii* , or else 73.2% if you add in a factor for preferential recovery. This second figure is very similar to the average make up in the coins from Pompeii, which was 74%.

This suggests that loss of different denominations is related directly to the proportions being carried around at the time; and not related to how often a particular denomination was being exchanged. The high numbers of *denarii* lost (many of which were recovered) relates to the need for individuals to carry larger numbers of higher value coins than we do today; because they, unlike us, did not have recourse to other financial mechanisms like the cheque book.

3.15 Conclusions

There are problems with the examination together of different denominations. Therefore in any model reconstructing the circulation of money the different denominations should be kept apart as far as possible so as not to include subjective assumptions about preferential recovery. However, the similarity of the breakdown of coins carried around in Pompeii and the reconstruction based upon site lists is encouraging.

The relationships which seem the most secure are the following: 'The more coins of series A in circulation, the more that will be lost'; and 'the longer coins of series A stay in circulation, the more that will be lost'. Preferential recovery is the third, though it is a relationship best avoided if possible as it includes too many unknown variables of human behaviour. Any new model must take account of these.

3.2 Site find database

In this section the site find database is discussed, its origins (3.21), its extension (3.22) and its structure (3.23).

3.21 Introduction

What is required is a representative sample of coins recovered from different types of sites throughout Britain. One large database already exists, developed principally for an analysis of fourth century coin, but containing first to third century data nonetheless. This was by collected Ryan (1988). This section describes how his database has been enhanced and extended to more than double its original size to cover a broader range of site both geographically and in terms of function.

3.22 The enhancement of Ryan's database

The primary basis of the database used in this thesis is an extended version of that compiled by Ryan (1988). His database comprised 8957 first to third century coins from 190 different sites. The sites were predominantly in the south of England, and therefore the corpus was lacking in military sites. To a lesser extent it also lacked material from *civitas* capitals and other major towns. Though some further data from the south of England has been included (principally Wroxeter), the majority of the additional sites are therefore from the North. Most are sites whose coins have been identified by Richard Brickstock and John Casey at Durham. The bibliographic details of these are given in Appendix 3.22. The bibliographic details of Ryan's original database can be found in Ryan (1988) by reference to the three figure site codes mentioned below.

The first to third century database now comprises 18,823 coins from 215 sites. The sites have been divided up into eight types. These are not the same categories as Ryan used. The new categories are: cemeteries, temples, villas, rural sites, military sites, and three classes of town site. The town sites have been divided into three categories: public towns, which comprise *Colonia* , Verulamium (a *municipium*) and *Civitas* Capitals; small towns and small towns where there has at any time been a military installation. These divisions have been done on the basis of the tables in Millett (1990). The sites are all listed in Appendix 3.21.

Table 3.21: Additions to Ryan's database

	Number of sites		Number of coins	
Type of site:	Ryan	Additional	Ryan	New Total
Cemetery	5	0	44	44
Military	3	13	121	1,107
Small Town with Fort	11	4	538	6,796
Small Town	9	1	531	572
Public Town	10	4	644	3,103
Villa	84	1	2,509	2,523
Temple	27	1	2,816	2,868
Rural	41	1	1,754	1,810
Total			8,957	18,823

3.23 Database structure

A number of changes were required to the original database. Ryan's principle interest was fourth century coinage. Here each coin generally had a unique reference number in RIC or LRBC. In the first to third century this is not the case. Some RIC numbers may refer to different denominations, though with the same obverse and reverse types; only the metal and/or unit size changes. Hence *aurei* and *denarii* sometimes cannot be told apart, similarly with certain types of bronze coinage. With the database being compiled for a fourth century analysis, the denomination column was sacrificed in the economy of space. Here it has been reinstated. Where possible all coins where there might have been any doubt as to which denomination they were have been traced back to their original publication. Alas frequently in vain as all toomany site lists simply give RIC numbers alone. Because this database specializes in first to third century coin, the mint column, especially important in fourth century studies, has been retained, though left unused. This is in the interests of compatibility with Ryan's database. Another new column is the 'accession number'. This is to facilitate cross referencing back to the original site list, should it be necessary. The number for all the new additions refers to the site list catalogue number. Checking Ryan's database made it all to apparent how useful a facility such as this would have been.

One major unsystematic error was found in the original database. This was the entry of coins of Gallienus. Gallienus and Salonina have two principle issues of coinage. One in their joint reign, and one in their sole reign. Both have separate RIC number sequences. This means that whether the coin is sole reign (SR) or joint reign (JR) must be specified. Frequently it was found that the database has bronze coins of Gallienus (SR) found on sites, however these are quite rare in Britain. On checking the original source, many of these were found to be JR, and others were quite probably misrecorded in the original site list. Two problems emerge. First the denominations of each coin looked up from the RIC number could be wrong; secondly the period the coins are ascribed to might be wrong. Gallienus (JR) is in Reece period 12 whilst Gallienus (SR) is in Reece period 13. To counter this problem two steps have been taken. First all the coins of Gallienus and

Salonina have been studied as one chronological group, thus precluding the possibility of any chronological mistakes. This is a pragmatic division rather than an ideal division which would lie precisely where Reece placed it. Secondly the references for every coin has been looked up under both JR and SR. In most cases both indicate the denomination to be an *antoninianus* ; however in the cases where a difference emerges the original reference has been sought.

Finally the most noticeable difference between this database and Ryan's is that instead of number codes being used for the catalogues and the degree of identification of each coin, a text string has been used. Though this takes up more space on disc, the advances in computer technology means that it is still perfectly possible to handle these larger files easily; and the words rather than codes makes the interrogation of the database easier.

Below are seven entries in the database. In this example the site database and the coin find database have been combined, though normally the site name, county and type of site would be stored in a second file, the site simply being referred to using its number. The columns are detailed down below:

Table 3.22: An example of seven entries from the database.

	Site	Site Name	County	Site Type	Acc.No.	Denomination	Ruler	Ruler Name	Boss

Field descriptions

Site: The site code. This number refers to Ryan's reference number for the site (Ryan 1988) or one of the additional sites referred to in Appendix 3.21.

Site Name: The name of the site

County: The county the site is in (post boundary changes)

Site Type: The functional type of site:

C = Cemetery, F = Military, U = Urban (Civitas capitals Etc.), S = Small towns, M = Towns either with an early fort or a strong military influence, T = Temple, V = Villa, R = any other rural site.

Acc.No.: For sites in Ryan's original database this was a numerical sequence given to the corpus as a whole. In the case of additional sites to the database, this refers to the original catalogue entry number to make cross referencing back to the original source easier.

Denomination: *Quadrans, As, Dupondius, Dupondius/As, Sestertius, Aes, Quinarius, Denarius, Antoninianus, Aureus*

Ruler: This is the code for the face on the coin (see Appendix 3.23)

Ruler Name: This is the name of the face on the coin (see Appendix 3.23)

Boss: The senior authority issuing the coin, eg. the Emperor in the case of a Caesar (see Appendix 3.23)

RP: The Reece period of each coin

Status: Blank or: As..., Var..., Copy..., Copy as....

Catalogue: The primary catalogue (if any), usually RIC or Crawford. All republican coins have been converted to Crawford, some references remain as BMC or Cohen references, though wherever possible Cohen references have been converted to RIC as well. If no catalogue identification has been made then 'none'.

Volume: The volume of the above catalogue. Not so important for 1st to 3rd century coins (except RIC 1 new and old edition), but vital for fourth century identifications.

Cat No.: Catalogue entry number

Letter: Catalogue entry letter (if any)

Number The number of coins of this type

Location The stratigraphic location of these coins (if any)

Note Reference to any notes on the entry kept elsewhere

Mint The mint at which the coin was issued. This column has not been used in this study, but is again vital for work in the fourth century.

3.3 Site find analysis

In this section the differential deposition of coin on different types of site is examined. Interpretations are made relating the nature of deposition to the integration of sites within the monetary economy. However, the study is essentially a traditional analysis based upon the static view of coin circulation (fig. 31.01). The limitations and problems of such an analysis are discussed and the need for a more dynamic model of circulation dynamics is called for.

3.31 The relative deposition of coin on sites

From the data in Appendix 3.21 the proportion of coin deposited on each type of site in each period can be established. This is shown in fig. 33.01. The first impression is of the overall regularity of the shape of the histograms. Though there are differences in the proportions between the various classes of site, the general tendencies are the same. The high presence of later Julio-Claudian coins on military sites is the most marked deviation. This period is mainly represented by Claudian copies (which are discussed further in section 4.1). Their dominance is partly a function of the inclusion of Usk in the database. However, it should be noted that this pattern shows through even though many of the rest of the military sites are from further north, in areas not occupied until after these issues had disappeared from circulation.

The military sites stand out in other periods as well. From the Republic until the early Severan period there is a higher proportion of coin lost on this kind of sites than any other. The only exception comes when examining the issues of Mark Antony, but even here his *denarii* are most prominent on small town sites where military establishments had existed. From the later Severan period onwards this trend is reversed, with forts displaying far fewer coins lost in virtually all periods. The single exception is the reign of Carausius and Allectus (the 'British Empire'). This pattern can be seen clearly on the graph, however direct comparisons between other classes of site are not so easy.

A second way of examining the differential deposition would be to look at the ratio of the number of coins lost on one type of site to that on another. Figs. 33.02-9 show just this. The construction of fig. 33.02 will be explained, then the trends in all of the studies summarized.

Fig. 33.02 shows period by period the ratio of coins in the database found on military sites, to those found in the public towns. For example, 19 Republican coins were found at forts, whilst 15 came from the public towns. The ratio is therefore 19/15 = 1.26. If

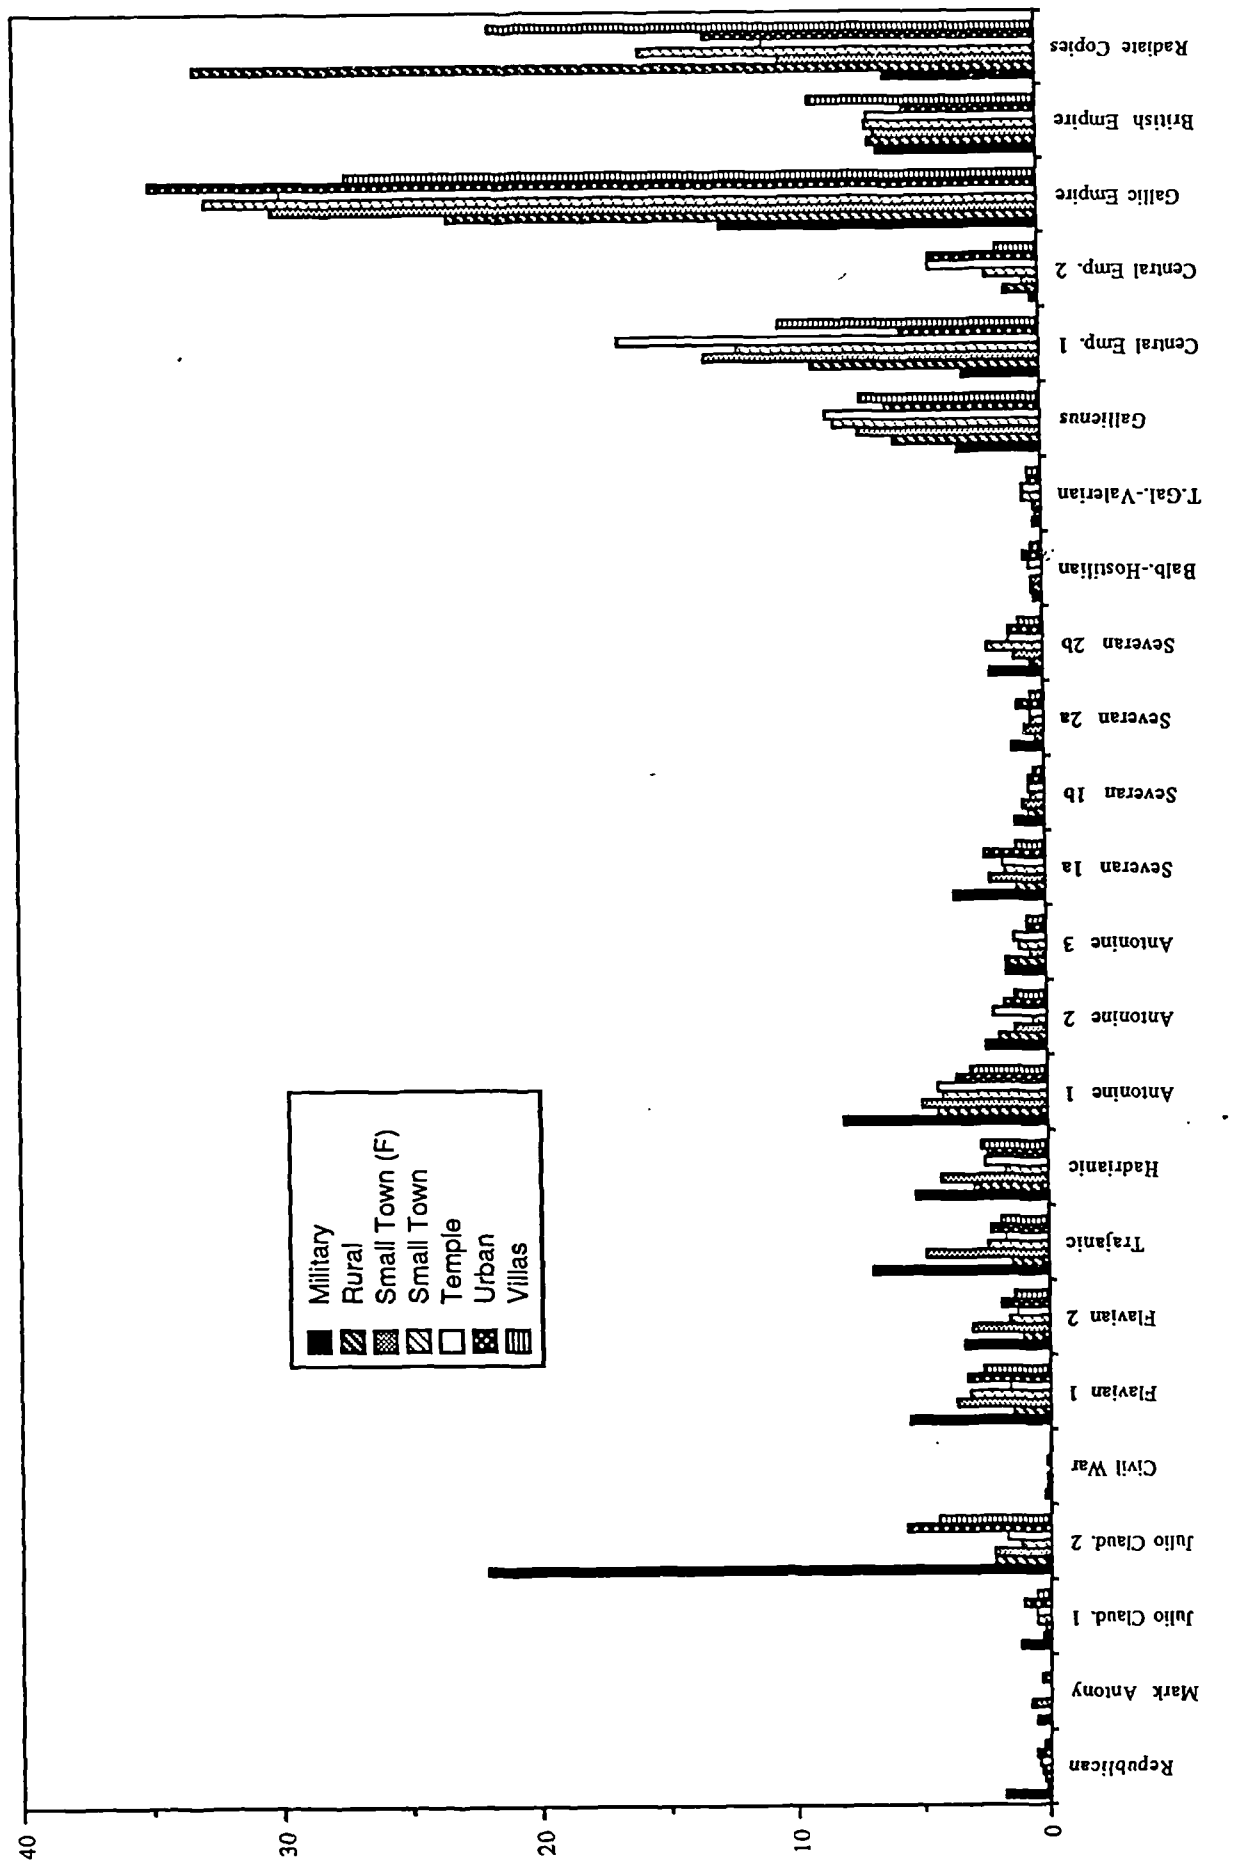

Fig. 33.01: The proportion of all 1st to 3rd century coins on sites.

the value increases from one date to another, it means that relatively more coins are being deposited on military sites than on town sites. If it decreases the pattern is reversed. It is a very simple use of the data. However, occasionally because of the small sample size some ratios can appear abnormally large or small. The only cases where this has happened has been in Mark Antony's coinage, during the civil war and the issues of Balbinus to Hostilian. In the case of the civil war coins here, 2 came from forts, whilst none were found in our sample of public town sites. This gives a ratio of infinity. Such values as infinity and zero, due to one of the sites having no coins of one period have been excluded from the histograms. What is important, however, is not the absolute values on any of these graphs, but any systematic trends which show up within them. Fig. 33.02 shows clearly that there is a shift in emphasis from coin loss on military sites to coin loss on Public Towns over time.

Fig.	Comparison between:	Trend
33.02	Military sites and public towns	Relative to military sites, there is an increase in coin deposition in the public towns during the 1st to 3rd century. The trend is weak to start with, however, the main change takes place from the early Antonine to the late Severan period. From Balbinus onwards the pattern is relatively stable, with a slight trough during the later Central Empire, balanced by a peak during the British Empire. The whole trend suggests a shift in the use of Roman coinage from the military to town life.
33.03	Small and public towns	Relative to public towns, there is a slight increase in coin deposition in small towns during the 1st-3rd century. The rise is clearer at the beginning than later on. This is consonant with the view of small towns being later developments than the civitas capitals.
33.04	Military sites and small towns with military associations	There is a rapid decline in the ratio of coin. This represents the temporary early nature of a lot of the forts in small towns of Southern Britain. The initial decline is matched by a second from the late Antonine period to the reign of Balbinus and Hostilian.

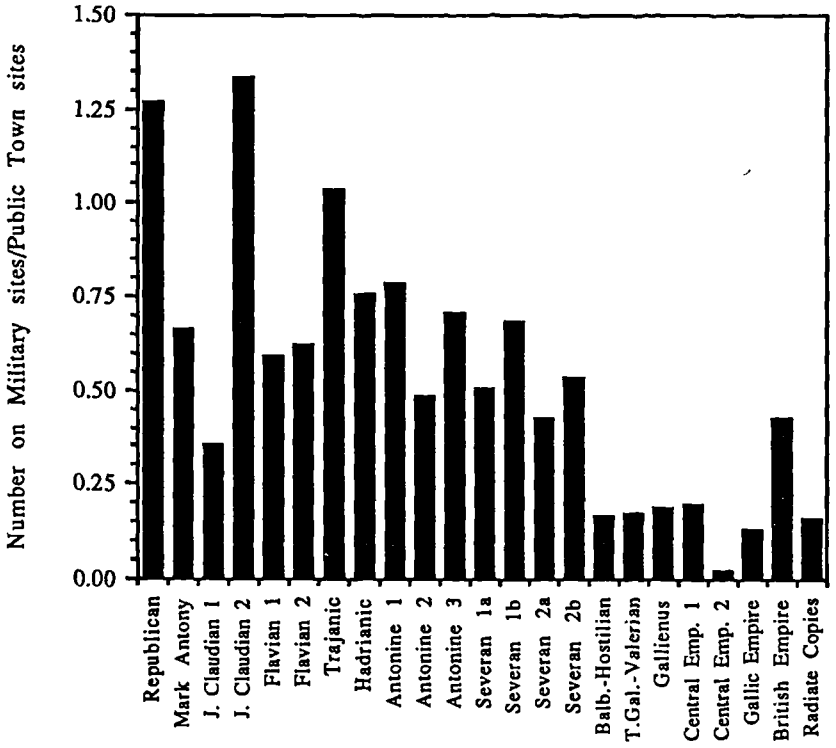

Fig. 33.02: The ratio of coins found in military sites and public towns.

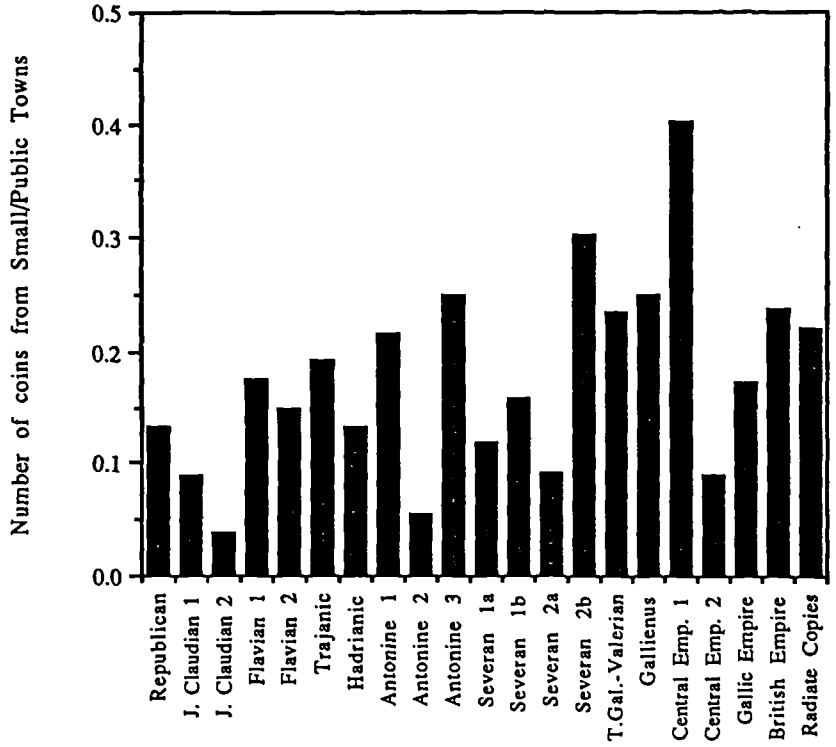

Fig. 33.03 The ratio of coins found in small towns and public towns.

33.05 Small towns with and without early forts

The small towns with military associations show a higher proportion of coin loss in the earlier period, this confirms the trend in figs. 33.02 & 33.04. Also it reflects the fact that many of the forts in the small towns were early affairs during the period of conquest, therefore it is in this early period when more coins would be deposited on sites.

33.06 Villas and public towns

The pattern here is slightly more complicated. From the conquest to the Hadrianic period there is a shift in deposition from public towns to villas, however, this falls in the Severan Period. Deposition on villas is strong again in the later third century, though with the exceptions of coins on the later Central Empire and Gallic Empire.

33.07 Villas and small towns

The ratio of coins between small towns and villas is virtually uniform. The large two value of Julio-Claudian 2 is a factor of a small sample size.

33.08 Rural sites and public towns

As with villas and public towns, the trend is not very clear cut. There is a shift from deposition in public towns to rural sites through to Antonine 3. In the Severan period fewer coins are found on rural sites. This grows again in the later third century, but as with villas, this excludes coins of the Later Central Empire and Gallic Empire. The trends are similar to those for villas and public towns, though the data are a little more variable.

33.09 Rural sites and small towns

There is a similar growth in the conquest to Antonine period, and a similar decline in the Severan period. However, the resurgence of deposition in the later third century is only marginally observed.

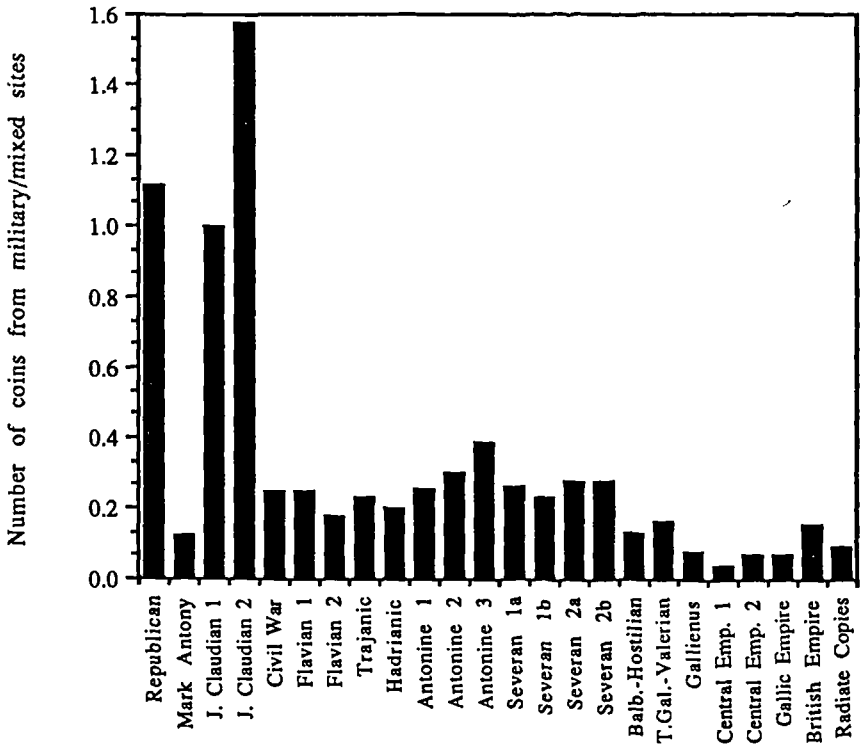

Fig. 33.04:
The ratio of coins found in military sites and small towns with military associations.

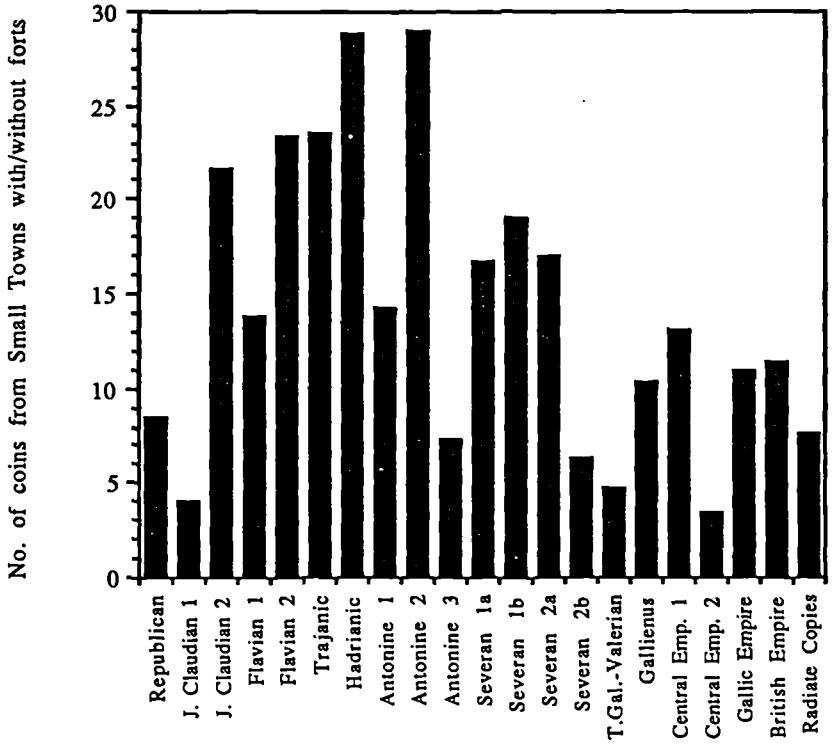

Fig. 33.05

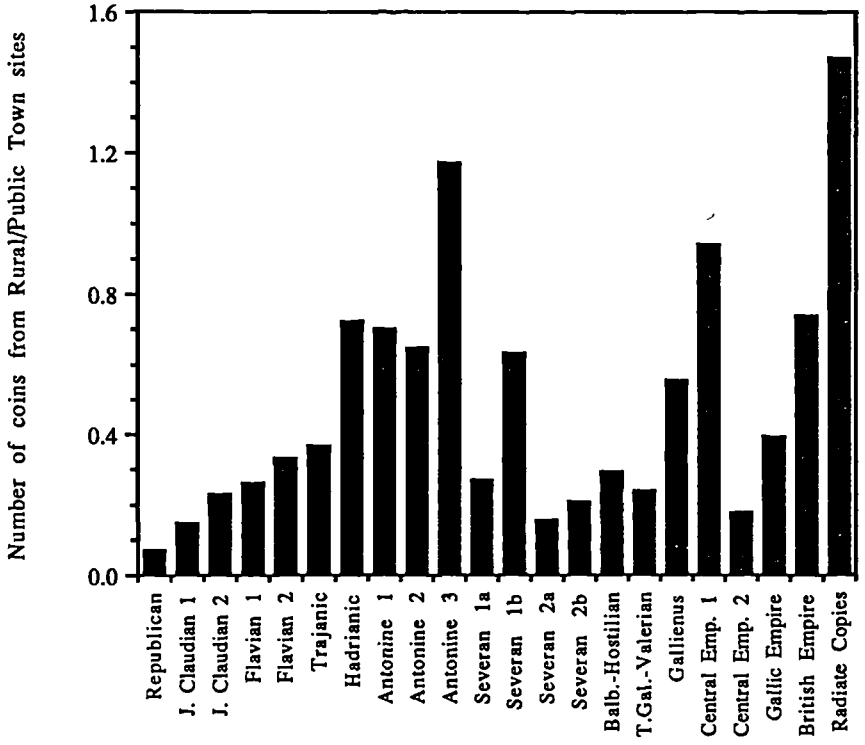

Fig. 33.08 The ratio of coins found on rural sites and in public towns.

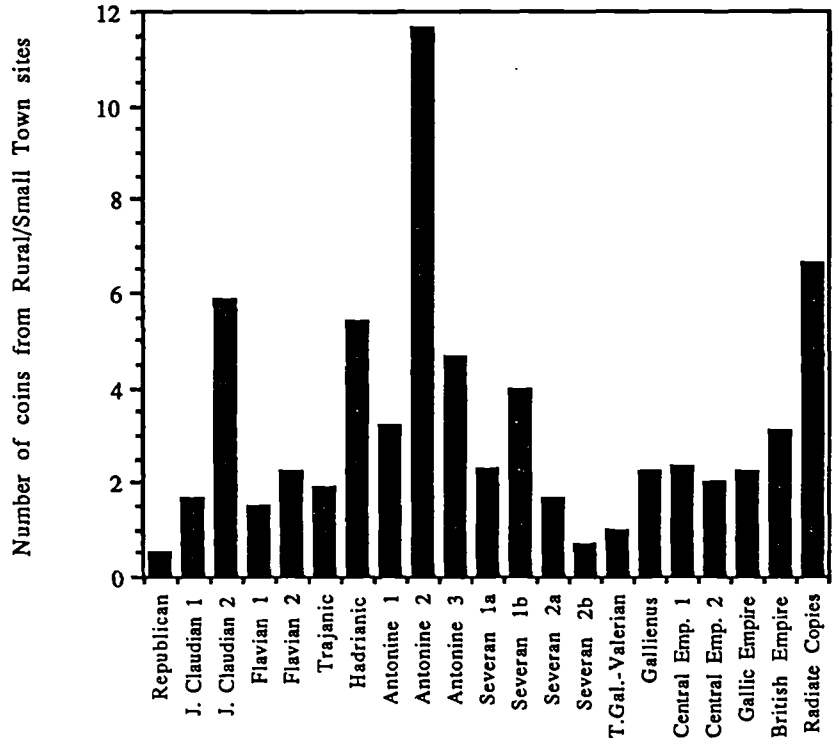

Fig. 33.09 The ratio of coins found on rural sites and in small towns.

33.10 Villa and rural sites

Here there is a clear shift in deposition from villas to rural sites from the conquest until Antonine 3. Then there is a slight reversal followed by a further decline.

In a lot of these cases the trends show a tripartite division. From the conquest to the Hadrianic or Antonine period, from then up to Balbinus and Hostilian, and from then up to the end of the third century. The trends have been schematized in fig. 33.11. There are three types of relationship shown. A solid arrow indicating a clear shift in emphasis of deposition from one type of site to another; a dashed arrow, indicating a less clear trend; and a dotted line indicating a stability in the ratio of coin deposition between the two.

3.32 Interpretation

Fig. 33.11 looks at the changing pattern of deposition of coinage on sites in three phases from the conquest to the late third century. First, what are the stable elements of the system? The only continuous link is that between small towns and villas. This shows a stability throughout the first to third century. This does not mean that equal numbers of coin were lost at each kind of site. All it means is that if the numbers of coin lost in the small town increased, so did that of the villas. The match possibly indicates a close relationship between the integration of both settlement types into the monetary economy.

Other rural sites have a flexible relationship with both villas and small towns. It appears that there was a relative increase in deposition on rural sites up until the mid second century, however then for a century this pattern reversed, only to be restored in the mid third century. One possible interpretation is that the initial rise reflected the growth in the countryside of the number of people handling coin. By the mid second century small towns and villas were becoming more prevalent. More villas were being constructed and small towns were playing a more important role in the distributional system. We have also established that in the second half of the second century *denarii* were circulating at their fastest ever rate. If this reflects an increase in the development of monetization then to see deposition at towns increase (both public and small towns) would be reasonable as more market transactions would be taking place here. In summary, the extension of the use of coinage first spreads into the rural population as more people are required to handle money to pay taxes; then later this extension of the monetary franchise stimulates the development of new market centres and larger productions of surpluses, which we see represented in the development of the small towns and villas. The shift in the ratio of coin deposited from rural sites to small towns

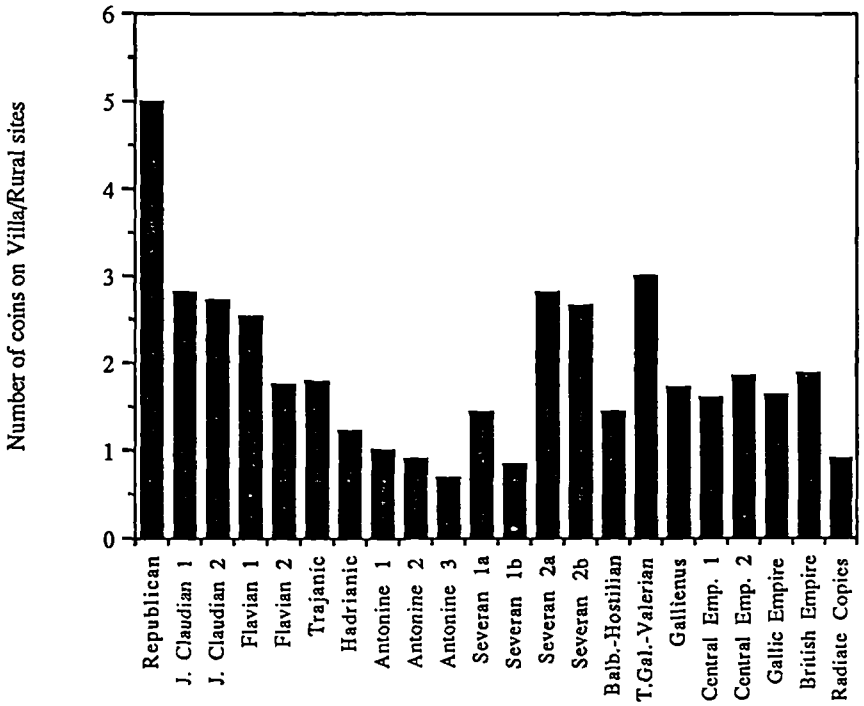

Fig. 33.10 The ratio of coins found in villa and on rural sites.

The shift in emphasis of coin loss from the conquest to the Hadrianic period:

The shift in emphasis of coin loss from Balbinus to the late third century:

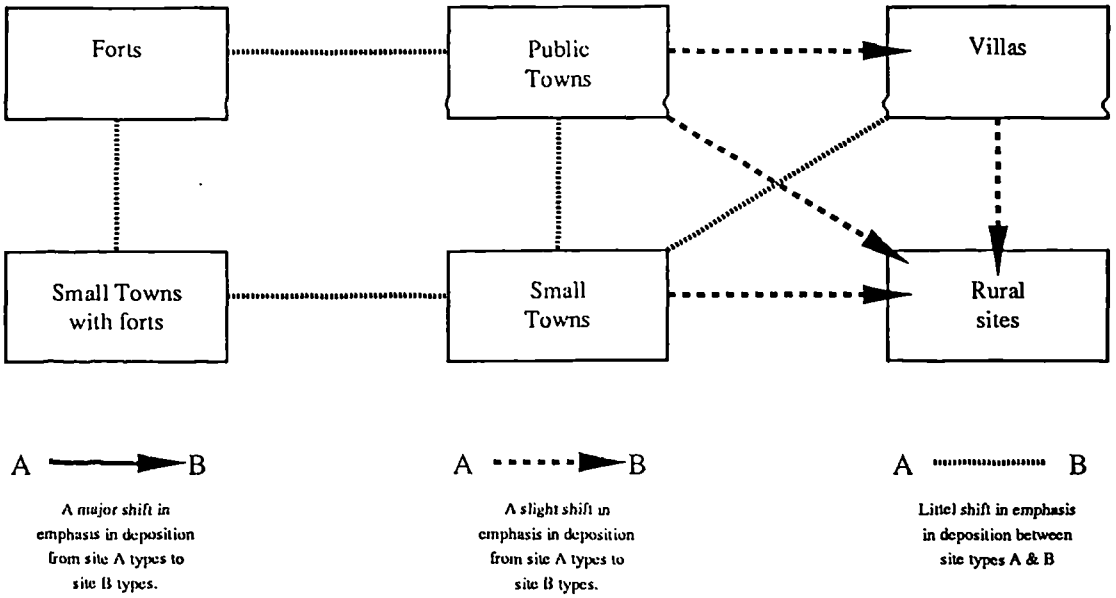

Fig. 33.11 The change in emphasis in coin loss on different types of site.

and villas is therefore more a factor of the later date of these market centres, than of any decrease in the participation of the countryside in the monetary economy. Of course this is only one possible interpretation.

In the later third century more coin is again found on rural sites. This comes with the mass production of *antoniniani*. It is noticeable that rural settlements have a higher proportion of radiate copies than any other type of site. Not far behind come villas. One explanation is that radiate copies were an acceptable medium of exchange in unofficial transactions, just as many tokens were in the 17th century. In the regulated markets of the towns such coin may not have been of as much use; however, out in the countryside they might have been acceptable. Hence most would be found on rural sites, then villas, then small towns and only then in the public towns. On the other hand people may have only realised they had been given fake coin in their change when they got home from the market and then just thrown it away. Both are quite possible. However, it is difficult to believe that owing to the large numbers of radiate copies that these were not an acceptable medium for many purposes.

The relationship between small towns and public towns shows the gradual rise of the small town in the economic system, though stability in the amount of coin deposition at each seems to have been achieved by the mid third century.

Forts also change substantially in their relationship to the other settlements. Initially there is a higher proportion of coinage being deposited there, but eventually an equilibrium is reached with the public and small towns in the mid third century. Since the army was one of the primary entry points in Britain of Roman coinage this early dominance is not unexpected; though as Roman coin use spread through the country after the conquest, one would expect the ratio to decline, as it does.

Basic coin loss, however, is only half the story. We may be able to see changes in the levels of deposition on rural and military sites, but what of the particular denominations that were being lost on each? Can this enhance our picture of the changing role of the different settlement types in the monetary economy ?

3.33 Denominational analysis: by site type

Some of the coins in the database are of unknown denomination, these therefore have had to be excluded, reducing our sample size slightly but not significantly. Other coins are recorded simply as *aes* . This means a division into *antoniniani, denarii, sestertii, dupondii* and *asses* is possible but very restrictive in its use of data. For looking at large scale trends a simple division into 'bronze' and 'silver' has been used (even

though many of the bronze coins were made of no such alloy, and many of the later silver coins were very base). The division is simple but useful.

The proportion of 'silver' from each period on each type of site has been established and is shown in Table 3.31 and figs. 33.12 & 33.13. The table only goes up to Valerian as after this virtually all the coins produced are of one denomination: the 'silver' *antoninianus* .

Fig. 33.12 looks at the relationship between military and town sites. The civil war coinage was principally one of *denarii*, these coins were only found on the military sites, and small towns with military influences. In the Flavian period these two types of site also had more silver present on them than the towns, and the mixed towns and forts seem to continue with a silver rich assemblage into the late Antonine period. The small towns and public towns have similar proportions of silver up until the Trajanic period, from whence the small towns tend to have a more silver deficient assemblage. This lasts into the start of the Severan period, when the provision of bronze coinage becomes very deficient on all types of site.

In summary what we see are town sites assemblages containing more 'small change' than military sites. Small towns with early forts belonging to the second category. Public and small towns have similar assemblages until the Trajanic period when more 'small change' starts to be deposited on small town site. This trend is seen continuing into the later third century where it vanishes due to the introduction of a virtually unidenominational currency system.

Fig. 33.13 looks at the relationship between town and country. The values for small towns and public towns are repeated here alongside rural sites and villas. The picture is generally very mixed. Up into the Flavian period there is a slight predilection for silver on country sites. The most early Julio Claudian silver is found on these sites, and Rural sites contain the most Claudian and Neronian silver. Civil war coinage is only found on the rural sites, and in the Flavian period villas have the highest proportion of silver. The trend, however, is not strong. From the Hadrianic to the early Severan period public town sites have the highest proportion of silver. Then as before, with the irregular supply of bronze to the provinces the picture gets a bit mixed.

In summary what we appear to see is country sites starting off with a more silver rich assemblage, whilst town sites produce marginally more 'small change'. In the Antonine period this picture reverses itself, and this position is possibly sustained into the later third century, though again this trend is weak.

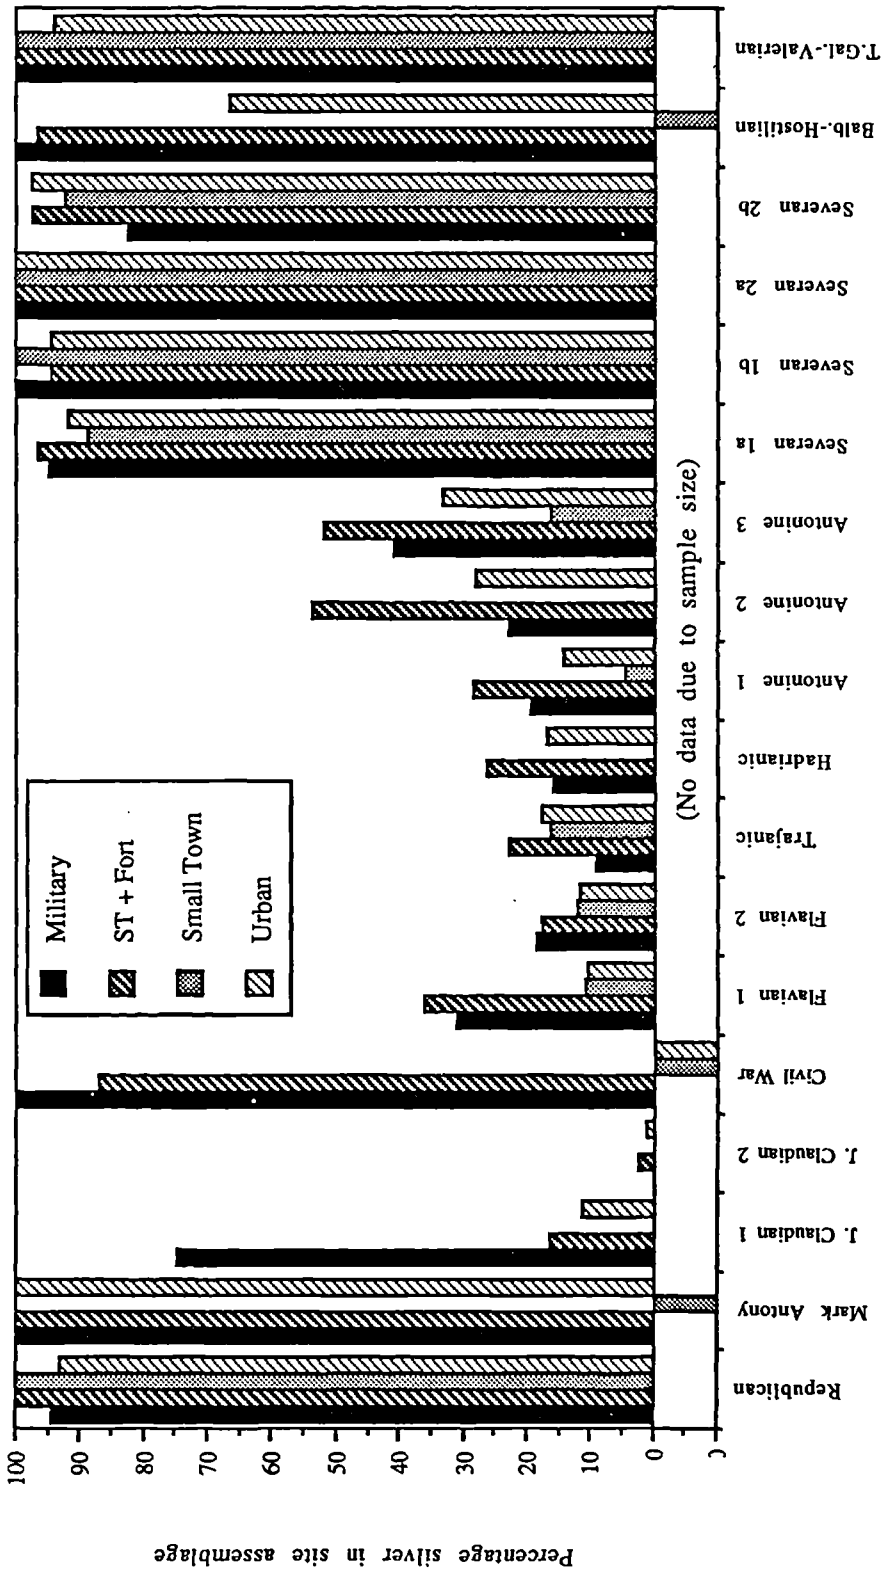

Fig. 33.12 The proportion of silver deposited on military and town sites.

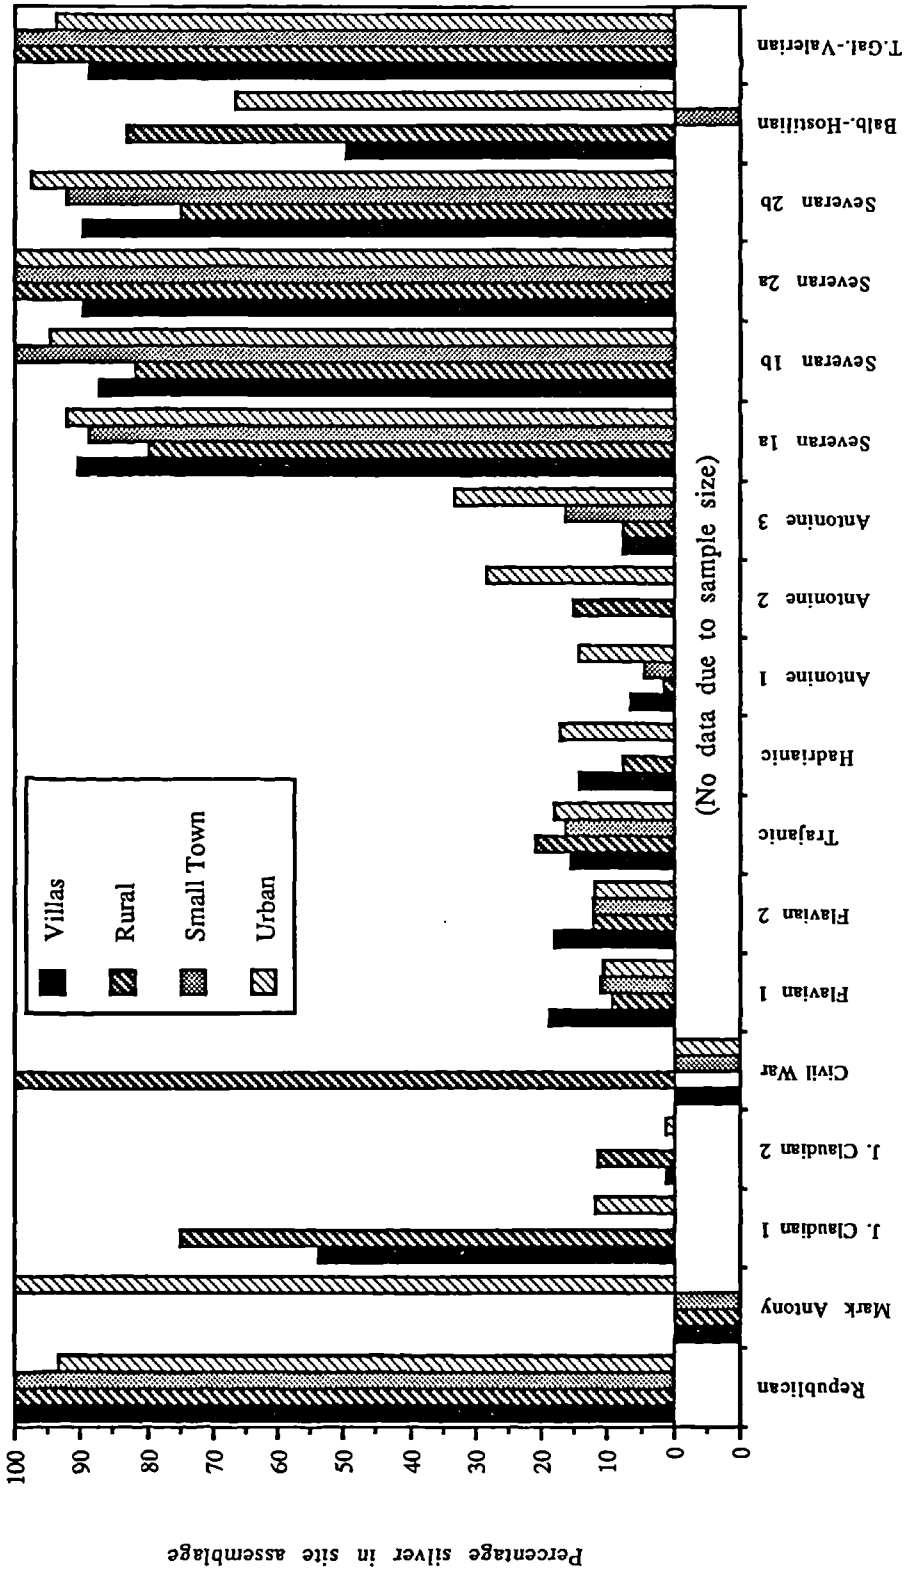

Fig. 33.13 The proportion of silver deposited on town and country sites.

Table 3.31: The proportion of silver coins in site assemblages, divided by the type of site.

Group	Period	Villa	Rural	Military	ST + Fort	Small Town	Public Town	Temple

R	T.Gal.-Valerian	88.89	100.00	100.00	100.00	100.00	94.12	100.00

In conclusion, analysing the proportion of silver in site assemblages by the type of site shows some variation. However, this variation is not clear cut. Those trends which do emerge are as follows:

1. From the conquest to the Trajanic period town sites contain a higher proportion of bronze coins in their assemblage than either military or rural sites.

2. From the Hadrianic period possibly continuing into the later third century, military sites continue to have the most silver. However, small towns and public towns now have more silver than the rural and villa sites. Even so small towns are closer in their make-up to rural and villa sites than the public towns are.

3.34 Warning

The analysis gives a vaguely consistent picture of money moving into the countryside and back into towns as towns develop. However, how real is any of this? The entire procedure is based upon the static view of coin circulation (cf. fig. 31.01). These neat chronological divisions we know are false, coins could circulate for generations before being melted down or lost. Given that the principle foundation of this analysis is false, can the results be trusted at all? The answer is probably not. What is really needed is a dynamic model of coin circulation, not a static one.

3.4 A new model of coin circulation

In this section we explore various concrete suggestions made to tackle the problem of residuality. These include Muller's, Collis', and Crummy and Terry's models (Muller 1968; Collis 1974; Crummy and Terry 1979). An entirely new model of circulation dynamics is called for; one which uses evidence and data that is already available, and one which fulfils the criteria that it can be tested and validated or nullified. One is then created; first expressed in words and ideas, then in mathematical terms and expressions.

3.41 Muller's Model

> "...before we can use coins except for the roughest kind of dating, we must not only have a large number of them and work according to sound general principles, we must also know how long they were in circulation: that is, what interval must be assumed between the time when they were minted and the time when they were lost."
>
> (Collingwood 1930, 187)

The feelings of pessimism expressed in the 'Coins and the Archaeologist' (Casey and Reece, 1974) papers some 44 years later suggest that Collingwood's simple question has yet to be answered. Residuality has been talked about, ideas have been suggested, but that extra step to convert those ideas into working models has not been taken except in the case of Muller (1968). His idea was neatly summarized by Crawford:

> "The principle involved may be roughly stated thus: the occupation can be identified as beginning with the first year for which the available coinage in the area is fully reflected on the site. For coinage may be presumed to begin to disappear from circulation by loss or hoarding immediately after being issued. If then a site comes into use on 1 January of a certain year, the coinage issued in that year will be the first one which is available in its entirety as a preliminary to representation on the site. If one plots, year by year, for the site and for the area as a whole, the volume of coinage as a percentage of the totals from the site and from the area, the date at which occupation of the site begins is indicated by the point where the two graphs coincide for the first time."
>
> (Crawford 1983, 202)

This is expressed in fig. 34.01. The model tries to establish a clearly defined 'start date' for the use of coinage on a site. However it requires that coinage is either fully used or not used at all. It would neither be able to cope with sites with variable levels of occupation and hence coin deposition; nor with changing levels of integration with the monetary economy. Nonetheless, the model is one which can be applied directly to coin data as it already exists; albeit in the restricted historical quest for the 'start date' of

Roman sites. Its best use would be in dating the start of military sites; but its use for other types of settlement could be questionable.

3.42 Collis' Model

We need models which can cope with a much broader range of questions than 'when did coin use on this site begin?' Collis (1974) presented two important ideas in his paper. First he created a visualization of a dynamic currency system. These images were similar to those which Haselgrove used (fig. 31.01; Haselgrove 1987, 35). Secondly he suggested a way of solving the residuality problem. He thought about using hoards as a basis, but dismissed them because of the variable nature of selection factors, as he perceived them. Instead he saw the future in seriation analysis of archaeologically associated groups of coinage:

> "The only way is to use the evidence of associations... [This can come] from pit groups and other associated finds which were lost over a short period of time. Every time two or more coins are found together in a pit or feature we have an association. There must be hundreds of such associations published and dozens more found each year, but no one has yet started to gather this body of data together"
>
> (Collis 1974, 182)

Alas, they had not gathered the data in 1974, nor have they since. Collis' plea for data went largely unheeded. However seriation is not the best method on a number of grounds. First the sheer quantity of data realistically needed is far more than a couple of hundred associations. Reece divided up Romano-British coinage into twenty-one periods, all about twenty years long. If we only ascribe our data to this coarse framework, and take into account the different denominations (as their longevity certainly differed) then we have at least fifty categories of data. This would require far more than a couple of hundred associations of a couple of coins on archaeological sites to achieve a sensible seriation. As Collis says: "To build up a trustworthy seriation, hundreds if not thousands of observations are needed of coins found in close association and obviously lost at the same time. The more observations, the less important become the statistical errors..." (Collis 1974, 182). Yet to be realistic, this would still only be with a coarse division of the data into coin periods. Individual emperors would require even more data.

Apart from the problem of gathering enough data, most seriation packages require various assumptions to be made about the data. Most seriation programs assume the categories of evidence to have normal distributions across time. Collis would certainly recognize that this is not the case. Coins (it is thought) have a rapid growth in the number in circulation and a long slow tail off. Perhaps this is more similar to a binomial distribution than an normal distribution. Yet even if a package were to sort the

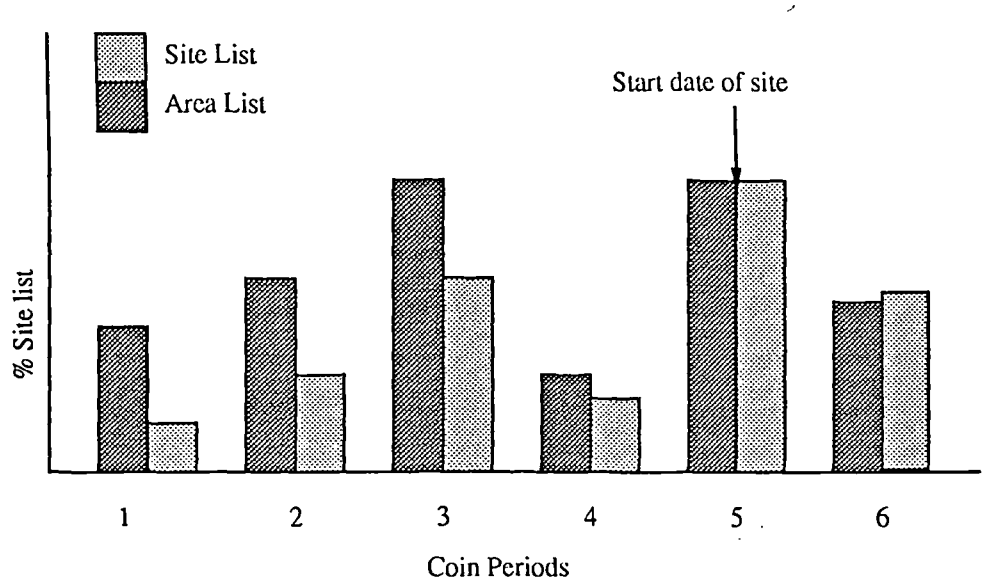

Fig. 34.01: Muller's model

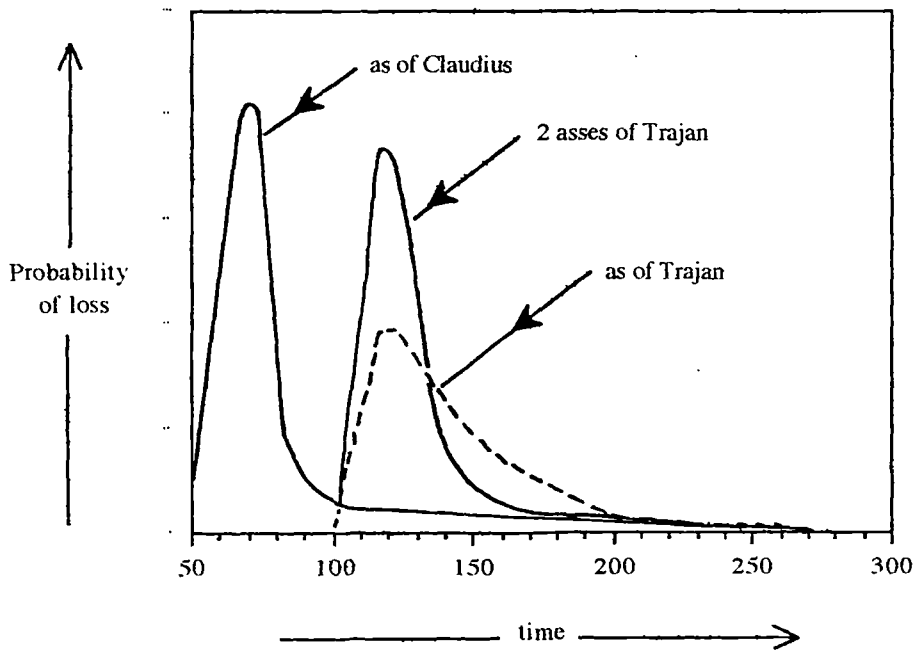

Fig. 34.02: Crummy and Terry's model: the frequency of some specific coin types in hoards through the Roman Period (Crummy & Terry 1979)

data on the basis of binomial distributions this too would be to force on the data a pattern which might not be there. Whereas the coins of Antoninus Pius might have a curve which approximate to a binomial distribution, others such as Republican coinage in Britain most assuredly do not (Reece 1974, 83).

The method has potential. Unfortunately it requires an enormous amount of as yet uncollected data. Also the seriation method would order the data by forcing it into preconceived patterns which might not be appropriate.

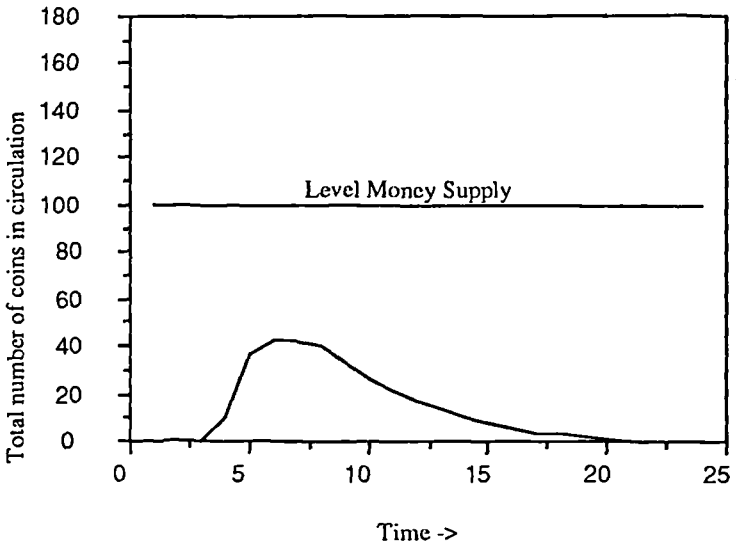
3.43 Crummy and Terry's Model

Crummy and Terry were also extremely interested in the possibilities of seriation (Crummy and Terry 1979). They called for the use of seriation on primary deposit groups of coinage as Collis had done, but then went on to mention another suggestion, based on hoard evidence:

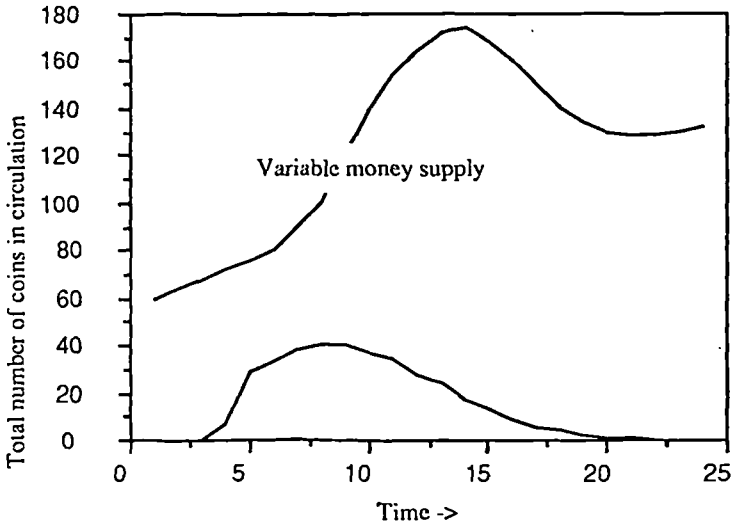
> "...we could probably obtain a graph for most types of coin showing frequency of loss against time by plotting for each type of coin the percentages present in coin hoards of various dates [cf. fig. 34.02]. In this case, one of the graphs represents the various grades of copies of Claudian asses, another graph a Trajanic as and a third curve two Trajanic asses. The area under each curve between any two points in time expressed as a proportion of the whole area under the curve represents the probability that any coin of that type from a class 1 context was dropped between those two times. Further, the area common to all these curves provides the means of calculating the probability of finding two Trajanic asses and one Claudian copy in the same class 1 context. As can be seen, the occurrence of such a possibility is small, so that in a case like this either the excavator is wrong in assuming that the context is class 1, or he or she was very unlucky."
>
> (Crummy and Terry 1979, 55)

The illustration, of course, did not come from real data. The authors qualified their suggestion by saying that of course hoards were highly selective and the study of hoards was full of all kinds of difficulties, but nonetheless their idea is very appealing. The possibilities it offers are exactly what archaeologists require. Whether there would ever be enough early imperial bronze hoards in Britain to construct such a graph is highly questionable; but it might be possible with *denarii* or with different emperors grouped together into coin periods.

Although the basic approach and ideal is correct, there lies in the method a much more serious error. The graphs they conceived did not show 'the frequency of loss against time' from which they could derive their probabilities as they imagined. The vertical axis, it must be remembered, is the percentage of coin present in hoards - not the absolute number in circulation. The probabilities can only be derived from the curve if it is assumed that the total number of *asses* in circulation in Britain remained constant, with losses and withdrawals from circulation exactly equalling the volume of newly



(A) The 'skew-curve' shaped distribution of a coin series in a period of level money supply; here the curve shown as a proportion of the money supply would have the same profile as it does now.



(B) Here, where the money supply varies, there becomes a difference between the profile of the actual skew curve shown here; and its shape if drawn a proportional scale. If the curve here was redrawn on a proportional scale, the profile would be exactly the same as the figure above. Distortion occurs.

Fig. 34.03 Distortions left in Crummy and Terry's model

minted coin entering circulation. This is highly unlikely, especially in early Roman Britain, where one might expect a growth in the volume of circulating coinage as society became more 'monetized' (though see section 4.3). Fig. 34.03 shows this kind of distortion. In fig. 34.03a the total volume of coins in circulation is constant, and so the two curves are identical; whereas in fig. 34.03b the total volume of coinage in circulation is rising, so our 'percentage in hoards' vertical axis is only a crude approximation to reality.

3.44 The requirements of a new model

The arguments over seriation require a new model not to make any assumptions about the shape of a coin loss curve. Many will perhaps be classic skew-curves (Collis 1974, 178), but not all of them will be. Political and economic forces may distort the shape of many of them, as specific coins are selectively called in. Also, the new model must take into account the variation in the total volume of coinage in circulation, and hopefully quantify this, as money-supply figures are potentially of great interest to us. And naturally, it must not go beyond the limits of the data as outlined in the previous sections.

The other main point is that the model should not just be a construction of one precarious piece of conjecture built upon another. It must be able to be tested:

> "...The crux of scientific procedure is that hypothesis (that is, the possible explanations or the possible laws) are formulated tentatively and then tested empirically. To test these trial explanations or possible laws, one first infers implications from them. These implications should pertain if the hypothesis is correct. Then one checks to see whether or not what these statements describe is actually the case.
>
> In the archaeological literature this procedure is often referred to as 'the hypothetico-deductive (H-D) method'..."
>
> (Watson et al. 1984, 12)

In order to avoid any kind of circularity, the data set the model is tested against must not have been used in any way to create the model in the first place. Only if predictions are derived from such a model, and these predictions compare well to the evidence, can our model be taken as validated... or at least, not invalidated:

> "...justification of a knowledge claim by formulation and testing of its implications ('It's so because these tests did not disconfirm it') is essential. One should not simply assert the truth of a knowledge claim ('It's so because I say so'). Formulation and empirical testing of hypotheses justify knowledge claims about the subject matter; untested assertions of knowledge claims do not."
>
> (Watson et al. 1984, 12)

3.45 The development of a model

To develop the model we will first hypothesize a monetary system with only one denomination. This consists of a series of issues from Coin Series 1 (C_1) to Coin Series n (C_n), this we will say has taken place over a number of years, from year 1 (T_1) to year t (T_t).

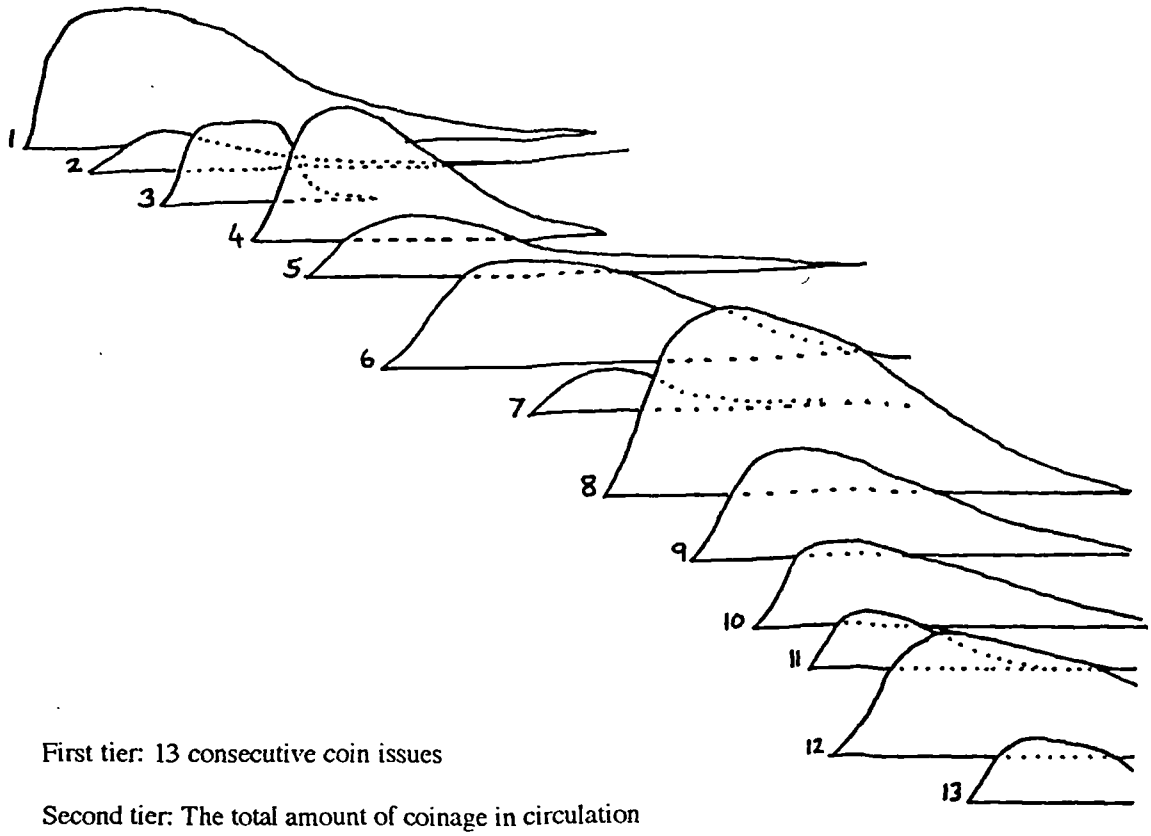
Unlike Collis' illustrated model (Collis 1974) where he had a series of penny issues all of which had identical 'number of coins in circulation' curves, reality will ensure that every issue will have a different curve. This diversity is expressed in fig. 34.04. The first tier of the diagram shows the skew-curves as Collis and Haselgrove would recognize them. They show the number of coins of each series in circulation over a period of time. As will be noticed, these cover a wide variety of shapes. Some issues are larger than others, others have irregular shapes. Coin Series 3, for instance, has been truncated as if the issuing authority behind it had become proscribed or undergone 'damnatio memoriae'; or it may be that the issue had more silver in it and was preferentially withdrawn from circulation.

The second tier shows the aggregate picture of the entire money supply. This simply comprises the earlier curves added together. The vertical scale here is the actual number of coins in circulation. It is, of course, simply an ideal construct. This is our eventual aim. If we ever had a picture like this we would have our money-supply figures and the means of quantifying residuality. However we do not have this kind of information for the present day, let alone for the Roman period.

The third tier shows the type of illustration which Crummy and Terry envisaged, though with all the coin series added together. It has exactly the same information content as the second tier, except that it is entirely devoid of any notion of the *total* volume of coinage in circulation, or of that total's variability. The vertical axis is the percentage composition of the circulation pool. Crummy and Terry equated this with the percentage composition in hoards.

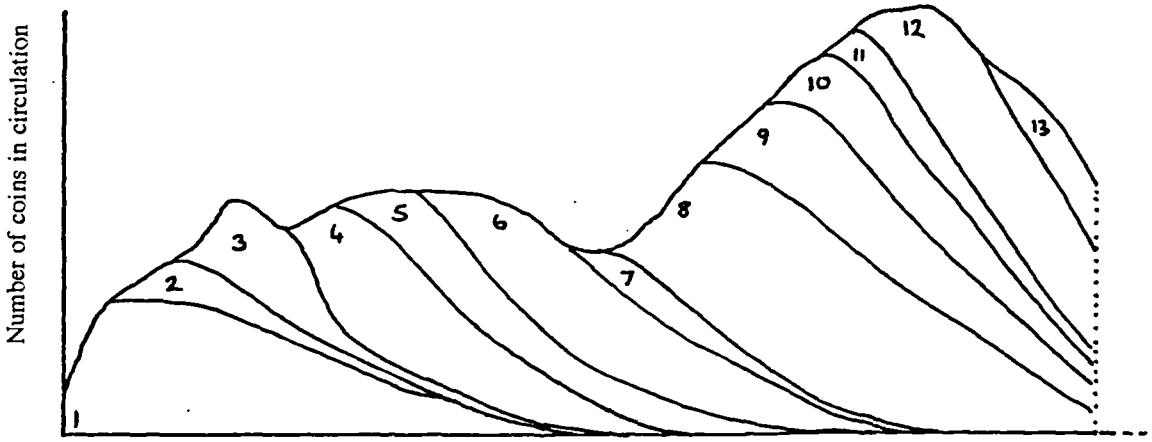
With this illustration in mind, what information do we know already? On the basis that hoards can sometimes be equated with the circulation pool, then we can draw the third tier for any individual denomination. For example, we did this for denarii in the first to third century in Britain (Section 2.4, fig. 24.05).

Unfortunately, as stated above, this tier is devoid of any notion of the total volume of coinage in circulation, or of its variability. Somehow we need information which can act as an input to convert our third tier to our second tier. This cannot come from



First tier: 13 consecutive coin issues

Second tier: The total amount of coinage in circulation



Third Tier: The proportional composition of the circulation pool

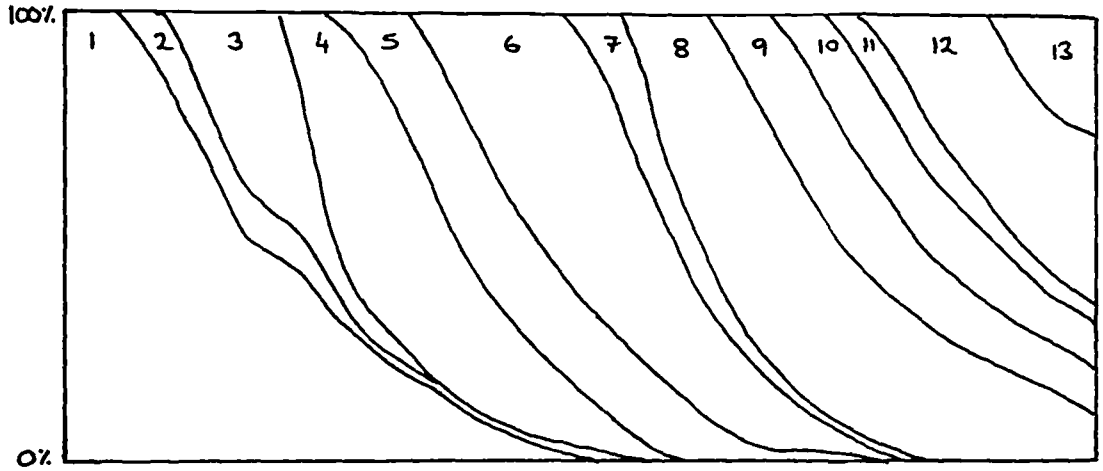


Fig. 34.04: The composition of the circulation pool

hoards. To use the total number of coins found in hoards of different dates to reconstruct the volume of coinage in circulation would be an entirely spurious exercise. The number of hoards found today, and their non recovery in antiquity, need have no direct relationship with the volume of money in circulation.

What does our second tier actually tell us? It visually describes the variation in the number of coins of any series in circulation over a period of time. Here I want to introduce the concept of 'coinage availability'. This is a variable which can be ascribed to any coin series. It is measured in coin-years (NOT 'coins per year'). One coin-year is a single coin in circulation for one year. Two coin-years could either be two coins in circulation for one year each; or one coin in circulation for two years. And so on. The two axes on our first and second tier model are 'time' and 'number of coins'. It therefore follows that areas on these graphs can be measured in such terms.

In our discussion of coin loss, we took our primary variables determining loss to be:

1. Loss of series A coins is proportional to the number of series A coins in circulation.
2. Loss of series A coins is proportional to the length of time the coins remain in circulation.
3. Loss of different coins *may* be inversely proportional to their intrinsic worth, due to preferential recovery.

The first and the second variable together state that 'loss is proportional to the number of coins and their duration in circulation'. Therefore if 1000 coins were in circulation for 10 years (10,000 coin-years), we would expect just as many to be lost as if there were 2000 coins in circulation for 5 years (also 10,000 coin-years), all things being equal. This requires no leap of logic, but is a direct consequence if variables 1 and 2 are believed. The areas on our first and second tier graphs are just such areas; though instead of being rectangles of X coins present over Y years, they are curves. Nonetheless, the argument is the same: the larger the area, the more coins are likely to have been lost, the smaller the area, the fewer the coins. Loss (leaving aside the variable for preferential recovery for a moment) is directly proportional to the 'coinage availability'.

This means that site finds can in theory provide us directly with information concerning our second tier. If the coins of each denomination are divided up into their different series, then the ratios of their abundance will equal the ratios of the areas on our first or second tier illustrations. The mathematics of this is described later; what is important at the moment is to convey the idea.

Now we have to account for the preferential recovery of different denominations. This exercise can only be done by looking at one specific denomination at a time, so this

problem is not great. If desired, it is perfectly possible to add in a correcting factor to site lists to account for preferential recovery. This could be based on the metrology and metallurgy of the coins as established by Walker (1976, 1977, 1978) for *denarii* .

From the ratios of the areas in our first and second tier, together with the information contained in our third tier graph, a full reconstruction of our second tier money supply can be created (the mathematics are described later). This can be done twice: first without taking into account a preferential recovery factor, and secondly with one. This would leave us with two sets of reconstructions of the money supply which could be tested against the data. There are three ways in which this can be done:

1. Excavated coin groups

As Collis suggested, excavated coin groups could be used to form a basis of a seriation analysis reconstruction of residuality; so can they be used to test this model? Crummy and Terry (1979) suggested ways in which a model like our second tier could be used to test the probability of finding a group of coins together. Crummy and Terry used the hypothetical example of a Trajanic and two Claudian *asses* . We could use real assemblages from primary contexts. The model which gave the real groups the highest probability of existing would be deemed best. However primary contexts are rare, and the chance of finding enough with multiple *denarii* in them is unlikely.

2. Sites occupied for short periods

A site, or group of sites (such as the Antonine Wall), which is known to have been occupied between relatively well-known limits can help us. If the date limits are inserted into our two models, each will predict the assemblage of coinage expected from the site. This can then be tested using chi-squared tests, against the actual assemblage present.

3. Coin Wear

This is a notoriously difficult aspect of coinage (see Section 2.3). Wear need not be proportional to the amount of time a coin was in circulation, since it is quite possible for a coin to have remained stationary in a hoard for long periods, while others ran around in circulation. Nonetheless, it is another possible way of seeing if our models approximate to reality. Large site lists, with consistent wear details recording them, can be analyzed. By dividing our second tier models into the individual coin series (tier one), we can hazard an approximation to the wear profile of the coins we would find on site. Again the two predictions can be compared to reality, and the best fit model chosen.

The details of each method are explained in Section 3.5. Ideally all should consistently point to one of the two models being preferential to the other.

3.46 The model in mathematical terms

The mathematical description of the model uses *denarii* in Britain as an example. The graphs which help explain it (figs. 32.04 to 32.09) are entirely conjectural. The circulation of the coins is looked at from AD 40 to AD 280.

Fig. 34.05 One of our aims is the creation of notional index of the money-supply figures for *denarii* in Britain. This notional index we shall call 'K'. K will have different values at different dates, and will be K_t at date 't'. This index needs to be anchored. Let us define K as being of unit value in AD 50. i.e.:

K_t = the notional index of the number of *denarii* in circulation at date t.

$$K_{50} = 1$$

The illustration shows the variation in the money supply figure K over time (to be precise, the graph in fact shows the variation of K multiplied by a factor of 100 - this does not materially effect the shape of the curve). As stated above, the graph is purely hypothetical at this stage. The Graph is the equivalent of our second tier illustration in fig. 34.04, though without the detailed breakdown shown.

Fig. 34.06 This illustration shows the make-up of the currency pool in terms of the different coins series or emperors that go to form it. C_n stands for Coin Series 'n'. Each coin series or emperor has a different integer value for n. For the sake of simplicity the earliest series is called C_1 and the rest, in order of their occurrence, are numbered sequentially. For our study of denarii C_1 would be Republican coins, C_2 *denarii* of Mark Antony etc..

Fig. 34.07 The previous graph can also be drawn as a proportional breakdown of what is in circulation (third tier), instead of on a relative scale (second tier). This graph can be derived from coin hoard data.

Fig. 34.08 This graph now needs to be described mathematically.

C_nT_t is defined as the percentage of the circulation pool taken up by coin series 'n' at time 't'. Therefore, at one date, say AD85, the following equation is true:

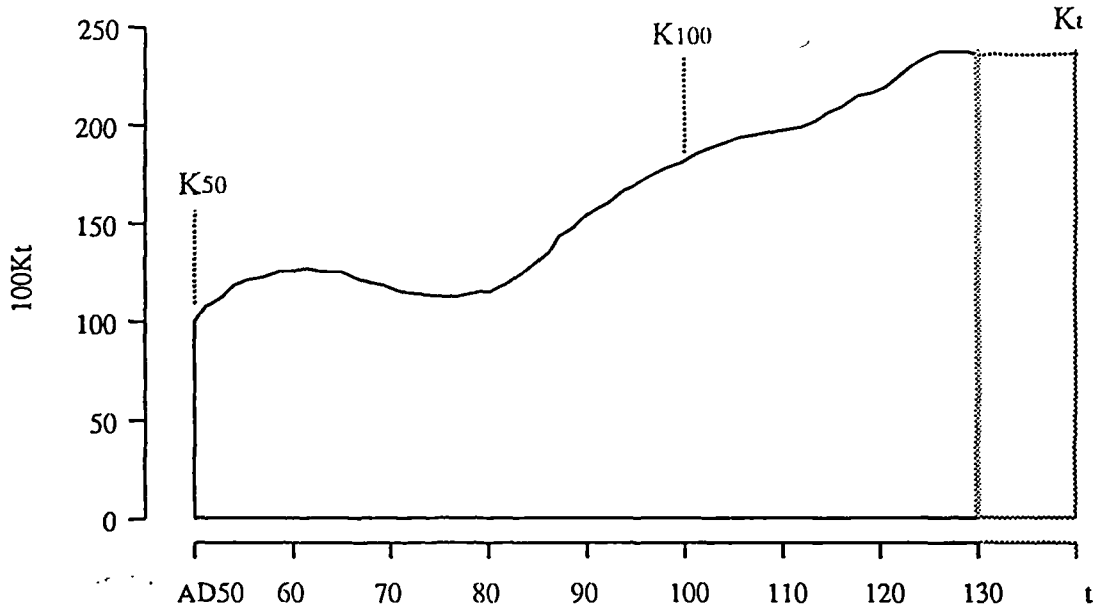

Fig. 34.05 K_t: the money supply index

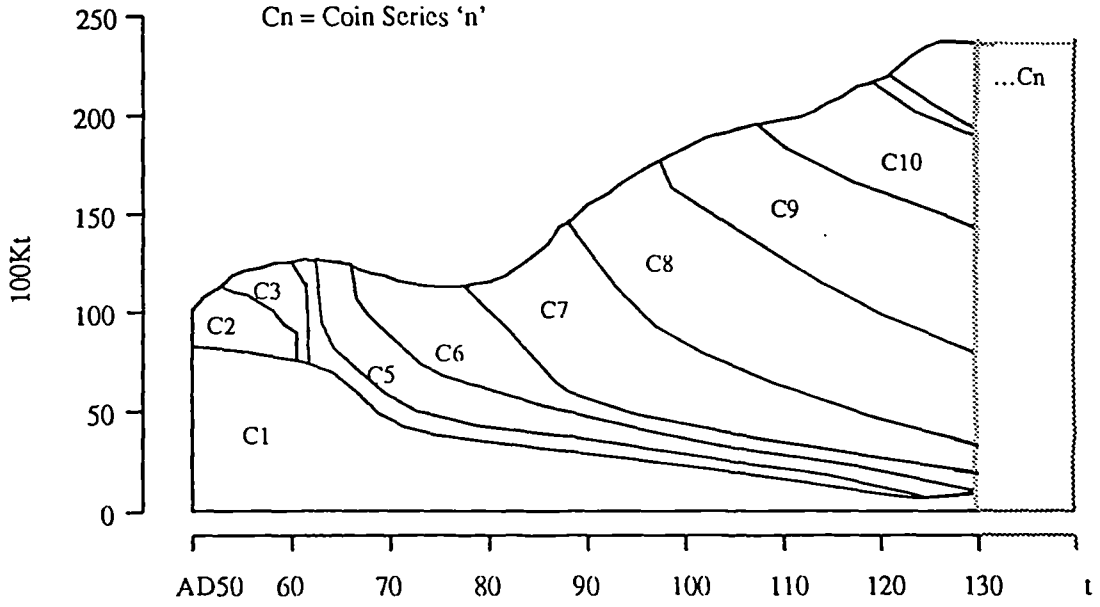

Fig. 34.06 The composition of the money in circulation

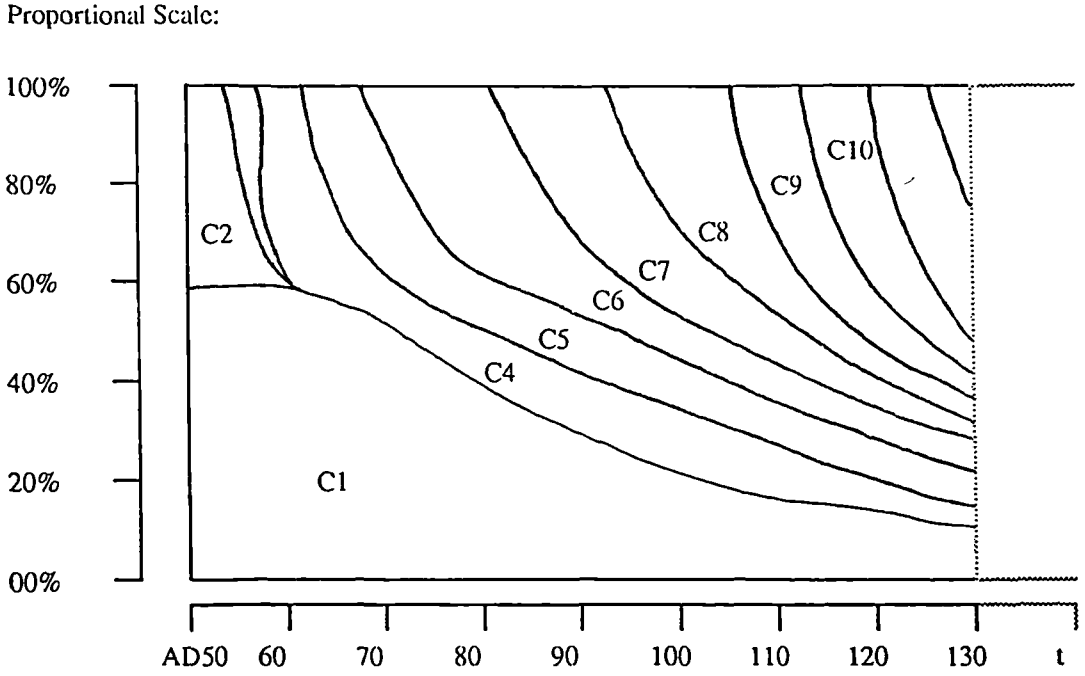

Fig. 34.07 The proportional composition of the circulation pool

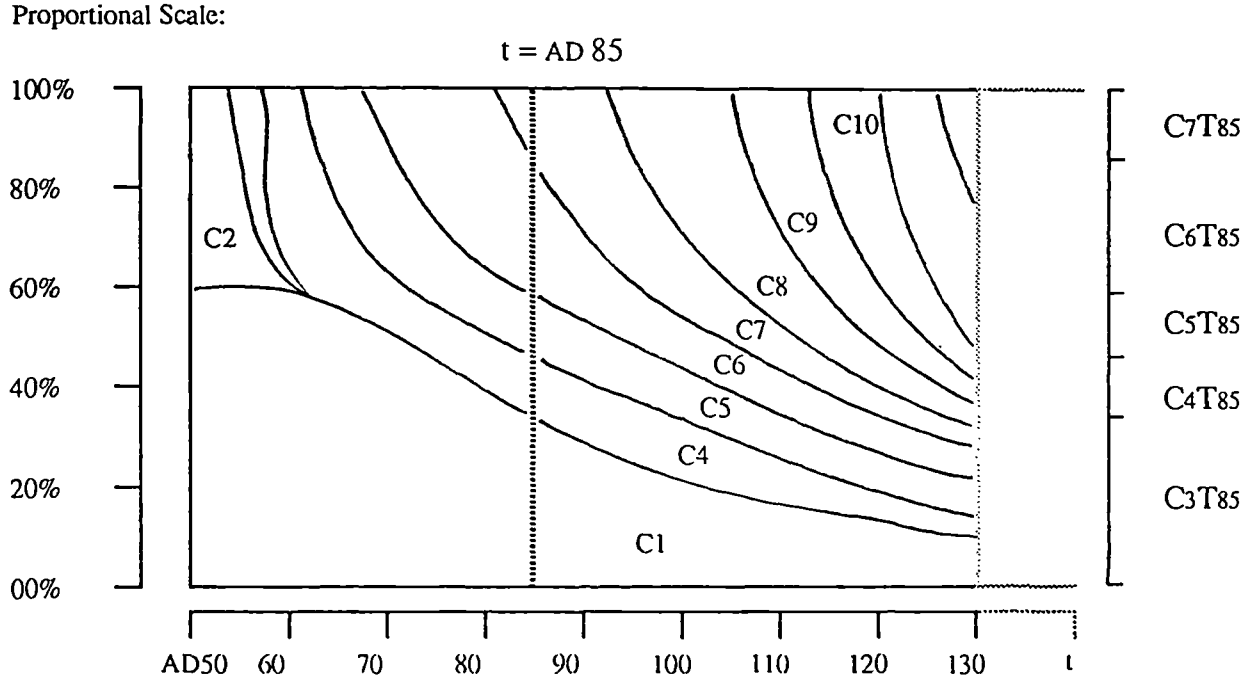

Fig. 34.08 Definition of C_nT_t

% of Coin Series 1 at AD85 +	C_1T_{85} +
% of Coin Series 4 at AD85	C_4T_{85}
% of Coin Series 5 at AD85	C_5T_{85}
% of Coin Series 6 at AD85	C_6T_{85}
% of Coin Series 7 at AD85	C_7T_{85}
100%	100

Or, in a shorthand form, for the year 't':

$$100 = \sum_{n=1}^{n=\infty} C_nT_t$$

The limits being the first to an infinite number of coin series is simply justified. In the case of AD85, the values of C_2T_{85}, C_3T_{85}, were zero, so they would not get counted, and likewise since series C_8 and above had not come into circulation yet, their values would also be zero.

In order to transfer our image of fig. 34.08 to fig. 34.06, we need to multiply all our C_nT_t values by our money supply index, K_t. Hence, it follows that:

EQUATION 1

Relative number of coins of C_1 around in AD85 +	$K_{85} \times C_1T_{85}$ +
Relative number of coins of C_4 around in AD85	$K_{85} \times C_4T_{85}$
Relative number of coins of C_5 around in AD85	$K_{85} \times C_5T_{85}$
Relative number of coins of C_6 around in AD85	$K_{85} \times C_6T_{85}$
Relative number of coins of C_7 around in AD85	$K_{85} \times C_7T_{85}$
Relative number of all coins around in AD85	$K_{85} \times 100$

Or, in a shorthand form, for the year 't':

$$100K_t = K_t \sum_{n=1}^{n=\infty} C_nT_t$$

Fig. 34.09 The areas on this graph express the availability of coin in coin-years; 'numbers of coins' and 'time' being the two axes. We need to establish the availability of each coin series to be lost. Therefore we need to create a formula which quantifies the area of each coin series on our second tier graph.

This can be approximated by dividing the area up into a number of vertical strips. Here we have arbitrarily decided to make the strips 5 years wide. The total area will be equal to the sum of all the individual strips. The area of each equals the height of each side added together and divided by two, then multiplied by five.

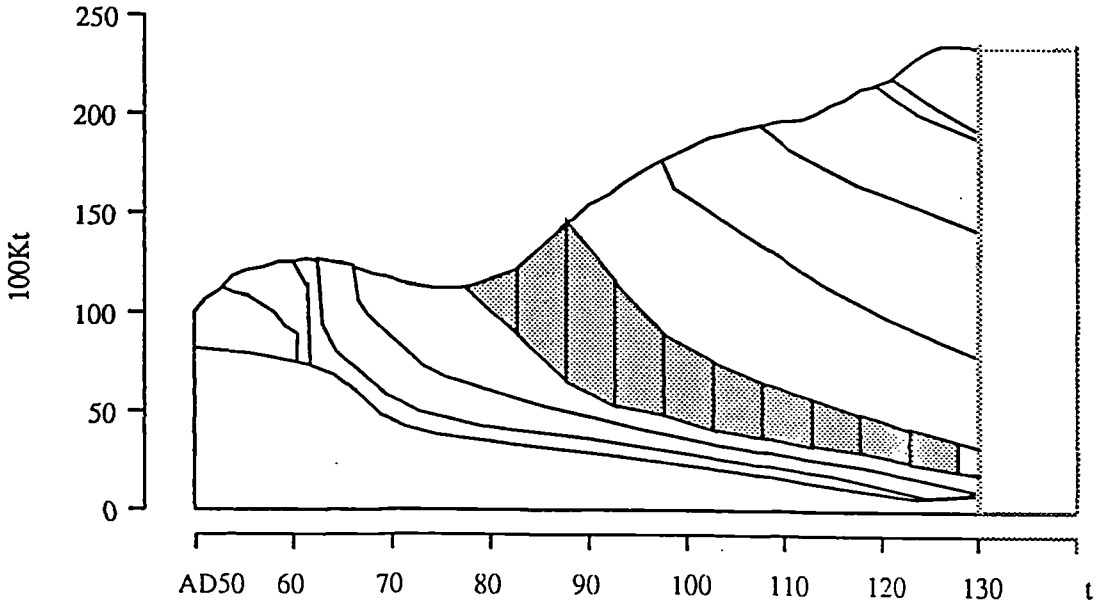

Fig. 34.09 The area on the graph representing Coin Series 7

Using the example of C_7; the area of a strip between date t and t+5 is:

$$\frac{((K_t \times C_7T_t) + (K_{t+5} \times C_7T_{t+5}))}{2} \times 5$$

The total area can therefore be established by equation 2:

EQUATION 2

Area covered by C7 in the 5 years in AD 80-85 +	$((K_{80} \times C_7T_{80})+(K_{85} \times C_7T_{85})) \times 2.5$
Area covered by C_7 in the 5 years in AD 85-90	$((K_{85} \times C_7T_{85})+(K_{90} \times C_7T_{90})) \times 2.5$
Area covered by C_7 in the 5 years in AD 90-95	$((K_{90} \times C_7T_{90})+(K_{95} \times C_7T_{95})) \times 2.5$
Area covered by C_7 in the 5 years in AD 95-100	$((K_{95} \times C_7T_{95})+(K_{100} \times C_7T_{100})) \times 2.5$
...etc	...
Area covered by C_7 in the 5 years in year t to t+5	$((K_t \times C_7T_t)+(K_{t+5} \times C_7T_{t+5})) \times 2.5$
Area covered by C_7 =	$2.5 \times \sum ((K_t \times C_7T_t)+(K_{t+5} \times C_7T_{t+5}))$

It follows that the availability or area of any coin series 'n' on the graph from AD 40 to AD 280 can be expressed as:

$$= 2.5 \sum_{t=275}^{t=40} ((K_t \times C_nT_t)+(K_{t+5} \times C_nT_{t+5}))$$

$$= 2.5 (K_{40} \times C_nT_{40} + K_{280} \times C_nT_{280}) + 5 \sum_{t=275}^{t=45} (K_t \times C_nT_t)$$

Equation 1 is the summary of the hoard data input. Equation 2 is our angle on the site find data input, though it has not been expressed in quite such terms yet. The two equations can be combined since they share a number of expressions in common. The combination (Equation 3) horizontally adds up to the areas of each coin series (Equation 2); vertically they add up to 100 multiplied by our money supply variable (equation 1), though with an additional constant of 5 years thrown in:

EQUATION 3

Area of C_1 =	$2.5 \times K_{40} \times C_1T_{40}$	$+ 5 \times K_{45} \times C_1T_{45}$	$+ 5 \times K_{50} \times C_1T_{50}$	$+...2.5 \times K_{280} \times C_1T_{280}$
Area of C_2 =	$2.5 \times K_{40} \times C_2T_{40}$	$+ 5 \times K_{45} \times C_2T_{45}$	$+ 5 \times K_{50} \times C_2T_{50}$	$+...2.5 \times K_{280} \times C_2T_{280}$
Area of C_3 =	$2.5 \times K_{40} \times C_3T_{40}$	$+ 5 \times K_{45} \times C_3T_{45}$	$+ 5 \times K_{50} \times C_3T_{50}$	$+...2.5 \times K_{280} \times C_3T_{280}$
Area of C_4 =	$2.5 \times K_{40} \times C_4T_{40}$	$+ 5 \times K_{45} \times C_4T_{45}$	$+ 5 \times K_{50} \times C_4T_{50}$	$+...2.5 \times K_{280} \times C_4T_{280}$
Area of C_5 =	$2.5 \times K_{40} \times C_5T_{40}$	$+ 5 \times K_{45} \times C_5T_{45}$	$+ 5 \times K_{50} \times C_5T_{50}$	$+...2.5 \times K_{280} \times C_5T_{280}$
Area of C_6 =	$2.5 \times K_{40} \times C_6T_{40}$	$+ 5 \times K_{45} \times C_6T_{45}$	$+ 5 \times K_{50} \times C_6T_{50}$	$+...2.5 \times K_{280} \times C_6T_{280}$
etc...	etc...			
Area of C_n =	$5 \times K_{40} \times C_nT_{40}$	$+ 5 \times K_{45} \times C_nT_{45}$	$+ 5 \times K_{50} \times C_nT_{50}$	$+...2.5 \times K_{280} \times C_nT_{280}$
Total area =	$2.5 \times K_{40} \times 100$	$+ 5 \times K_{45} \times 100$	$+ 5 \times K_{50} \times 100$	$+...2.5 \times K_{280} \times 100$
Total area =	$250 (K_{40} + K_{280})$	$+ 500 \sum K_t$ (where t = 45 to 275)		

This equation describes the make up of the number and types of *denarii* in circulation in Roman Britain.

Which of the variables do we know ?

Values of K_t This is the variable we are interested in finding out, since it represents an index of the numbers of *denarii* in circulation in Britain at date 't'.

Values of C_nT_t These we can create from drawing a third tier illustration from hoard data. For *denarii* in Britain this was done in Section 2.4 (fig 24.05, Appendix 2.42).

Area of C_n This represents the availability of coin series 'n'. This we have taken to be proportional to the number of coins lost, with the potential of adding in a factor to represent preferential recovery. For the moment, let us imagine we can get find a value to fit into this variable. If that is the case, then the only unknowns left are the values of K_t. Hence we have a long series of simultaneous equations to solve. Once done, we have a picture of the variation of the Romano-British *denarius* supply.

Obtaining values for 'area of C_n'

Firstly, a corpus of site losses has to be built up which reflects the standard pattern of coin loss in Britain. The specific way each corpus has been created is explained as each denomination is analyzed. The final form of the data will be a percentage breakdown of that denomination into their respective coin series:

Let SF_n be the percentage of coin series 'n' in our site find corpus for that denomination.

Hence:

Percentage of coin series 1 in list	=	SF_1 %
Percentage of coin series 2 in list	=	SF_2 %
Percentage of coin series 3 in list	=	SF_3 %
Percentage of coin series 4 in list	=	SF_4 %
Percentage of coin series 5 in list	=	SF_5 %
etc...		
Percentage of coin series n in list	=	SF_n %
Total number of coins in list	=	100 %

If no 'preferential recovery' factor is to be included, then this set of figures can continue in the analysis unadjusted. However if preferential recovery is called for then a modifying variable is required. Let this be R_n, for coin series 'n'.

In the case of *denarii* , the higher the silver content, the more coins we would expect to be recovered, therefore fewer would be found as site finds. A good approximation to

this would be to say that the chances of a coin being totally lost is inversely proportional to a coins silver content.

Therefore to get from our values of SF_n (which represent what was lost after the better coins had been recovered), to a variable representing what was initially lost, we need to multiply our SF_n value by a variable representing the intrinsic value of each coin series.

This is done by multiplying all our values of SF_n by R_n, which we shall define as the silver content in grammes of a series 'n' *denarius* . Then the modified values of SF_n can be reconverted into percentages; now to be called MSF_n (modified site find - MSF). This can best be shown by a hypothetical worked example:

Let us say that in a series of 5 issues:

Percentage of Site Finds:		Silver content:	
SF_1 =	20%	R_1 =	2.00 g
SF_2 =	32%	R_2 =	1.85 g
SF_3 =	22%	R_3 =	1.80 g
SF_4 =	17%	R_4 =	1.70 g
SF_5 =	9%	R_5 =	1.65 g
Total	100 %		

If preferential recovery is proportional to a coins silver content, then Loss will be inversely proportional to this factor. Therefore, in order to get back to the original pattern of 'loss' we need to multiply SF_n by R_n and recalculate the group as percentages:

$SF_1 \times R_1$	=	20 x 2.00	=	40.00	Therefore: MSF_1 =	21.91 %
$SF_2 \times R_2$	=	32 x 1.85	=	59.20	Therefore: MSF_2 =	32.43 %
$SF_3 \times R_3$	=	22 x 1.80	=	39.60	Therefore: MSF_3 =	21.70 %
$SF_4 \times R_4$	=	17 x 1.70	=	28.90	Therefore: MSF_4 =	15.83 %
$SF_5 \times R_5$	=	9 x 1.65	=	14.85	Therefore: MSF_5 =	8.13 %
		(Total	=	182.5)	(Total	100.00%)

As can be seen, MSF_1 (21.91%) is slightly higher than SF_1 (20 %), this is because originally more Series 1 coins would have been lost; but because the coin had a higher silver content, losses of it were searched for more carefully and more recovered. The reverse picture is shown by MSF_5 and SF_5, having a lower silver content.

We now have two sets of variables: both are percentage breakdowns of the different coin series:

SF_n represents directly the site find lists, and ignores any 'preferential recovery factors'.

MSF_n represents a modified site find list, and accounts for preferential recovery on the basis that coins are searched for in proportion to their intrinsic value.

The main variables accounting for site losses were thought to be:

1. Loss is proportional to number of coins in circulation
2. Loss is proportional to the duration of coins in circulation
3. Loss may be affected by the preferential recovery of higher value coins

The belief or not in variable three determines whether the SF_n values are used in the further study, or the MSF_n values. From here on it will be assumed the unmodified values are being used; though MSF_n values should be used in place of SF_n values should variable three be believed.

Since loss is proportional to both the number of coins in circulation, and their duration in circulation, we can express this in the form of an equation:

SF_n = constant x {(the number of C_n coins in circulation) x (the duration of C_n coins in circulation)}

The product of these two variables represents the availability of the coinage measured in coin-years. This is the variable we are after to represent the areas on our second tier graph. So, using a new constant 'Z':

$Z \times SF_n$ = 'Area of C_n'

As yet we do not know the value of our constant 'Z'. Nonetheless we can insert these new values into our Equation 3 to form:

EQUATION 3a:

$Z \times SF_1 =$	$2.5 \times K_{40} \times C_1T_{40}$	$+ 5 \times K_{45} \times C_1T_{45}$	$+ 5 \times K_{50} \times C_1T_{50}$	$+...2.5 \times K_{280} \times C_1T_{280}$
$Z \times SF_2 =$	$2.5 \times K_{40} \times C_2T_{40}$	$+ 5 \times K_{45} \times C_2T_{45}$	$+ 5 \times K_{50} \times C_2T_{50}$	$+...2.5 \times K_{280} \times C_2T_{280}$
$Z \times SF_3 =$	$2.5 \times K_{40} \times C_3T_{40}$	$+ 5 \times K_{45} \times C_3T_{45}$	$+ 5 \times K_{50} \times C_3T_{50}$	$+...2.5 \times K_{280} \times C_3T_{280}$
$Z \times SF_4 =$	$2.5 \times K_{40} \times C_4T_{40}$	$+ 5 \times K_{45} \times C_4T_{45}$	$+ 5 \times K_{50} \times C_4T_{50}$	$+...2.5 \times K_{280} \times C_4T_{280}$
$Z \times SF_5 =$	$2.5 \times K_{40} \times C_5T_{40}$	$+ 5 \times K_{45} \times C_5T_{45}$	$+ 5 \times K_{50} \times C_5T_{50}$	$+...2.5 \times K_{280} \times C_5T_{280}$
$Z \times SF_6 =$	$2.5 \times K_{40} \times C_6T_{40}$	$+ 5 \times K_{45} \times C_6T_{45}$	$+ 5 \times K_{50} \times C_6T_{50}$	$+...2.5 \times K_{280} \times C_6T_{280}$
etc...	etc...			
$Z \times SF_n =$	$5 \times K_{40} \times C_nT_{40}$	$+ 5 \times K_{45} \times C_nT_{45}$	$+ 5 \times K_{50} \times C_nT_{50}$	$+...2.5 \times K_{280} \times C_nT_{280}$
Total area =	$2.5 \times K_{40} \times 100$	$+ 5 \times K_{45} \times 100$	$+ 5 \times K_{50} \times 100$	$+...2.5 \times K_{280} \times 100$

Total area = $250 (K_{40} + K_{280})$ $+ 500 \sum K_t$ (where t = 45 to 275)

This equation can be simplified, Let $Q_t = (5 \times K_t)/Z$

$SF_1 =$	$0.5 \times Q_{40} \times C_1T_{40}$	$+ Q_{45} \times C_1T_{45}$	$+ Q_{50} \times C_1T_{50}$	$+...Q_t \times C_1T_t$	$+...0.5 \times Q_{280} \times C_1T_{280}$
$SF_2 =$	$0.5 \times Q_{40} \times C_2T_{40}$	$+ Q_{45} \times C_2T_{45}$	$+ Q_{50} \times C_2T_{50}$	$+...Q_t \times C_2T_t$	$+...0.5 \times Q_{280} \times C_2T_{280}$
$SF_3 =$	$0.5 \times Q_{40} \times C_3T_{40}$	$+ Q_{45} \times C_3T_{45}$	$+ Q_{50} \times C_3T_{50}$	$+...Q_t \times C_3T_t$	$+...0.5 \times Q_{280} \times C_3T_{280}$
$SF_4 =$	$0.5 \times Q_{40} \times C_4T_{40}$	$+ Q_{45} \times C_4T_{45}$	$+ Q_{50} \times C_4T_{50}$	$+...Q_t \times C_4T_t$	$+...0.5 \times Q_{280} \times C_4T_{280}$
$SF_5 =$	$0.5 \times Q_{40} \times C_5T_{40}$	$+ Q_{45} \times C_5T_{45}$	$+ Q_{50} \times C_5T_{50}$	$+...Q_t \times C_5T_t$	$+...0.5 \times Q_{280} \times C_5T_{280}$
$SF_6 =$	$0.5 \times Q_{40} \times C_6T_{40}$	$+ Q_{45} \times C_6T_{45}$	$+ Q_{50} \times C_6T_{50}$	$+...Q_t \times C_6T_t$	$+...0.5 \times Q_{280} \times C_6T_{280}$
etc...	etc...				
$SF_n =$	$0.5 \times Q_{40} \times C_nT_{40}$	$+ Q_{45} \times C_nT_{45}$	$+ Q_{50} \times C_nT_{50}$	$+...Q_t \times C_nT_t$	$+...0.5 \times Q_{280} \times C_nT_{280}$
Total =	$0.5 \times K_{40} \times 100$	$+ Q_{45} \times 100$	$+ Q_{50} \times 100$	$+...Q_t \times 100$	$+...0.5 \times Q_{280} \times 100$

Total area = $50 (Q_{40} + Q_{280})$ $+ 100 \sum Q_t$ (where t = 45 to 275)

We know all our SF_n values, and our C_nT_t values, so we are left with a large number of simultaneous equations to solve. After which we have a full series of results for Q_t.

At the beginning we defined K_t as our money supply index. This index was anchored by saying that at AD50 it was unity (i.e. $K_{50} = 1$). After solving the above equations, we will have a value for Q_{50}. Since we defined Q_t as being $(5 \times K_t)/Z$, we can calculate Z:

$$Z = (5 \times K_{50})/Q_{50}$$

Once Z has been found we can calculate all our values of K_t, the *denarius* supply curve, and will hence have achieved one of our primary tasks.

This is the theory. In practise, of course, one can do no such thing. The problem is the penultimate stage, solving the simultaneous equations. In order to do this you need more equations than unknowns. The number of equations is defined by the number of *denarius* groups, which is 17. However if our curve, K_t, is broken down into five year divisions from AD 40-280 this gives 49 unknowns. This means that an exact curve cannot be generated this way. However an approximation can still be arrived at.

The basic principle involved in coming to a solution is that the ratio of the Areas of C_n should be equal to the ratio of values of SF_n, as stated in the equation $Z \times SF_n$ = 'Area of C_n'. The ratios of SF_n are fixed, determined by the number of *denarius* site finds. The ratios of 'Areas of C_n' however will vary depending upon the shape of the *denarius* supply curve K_t, which it is our aim to find out. In theory the shape of curve K_t is correct when the ratios of both variables are identical.

A procedure can therefore be developed whereby a series of curves are given to represent K_t. The closest fitting curve is then calculated by comparing the similarity between the SF_n values and the 'Area of C_n' values using the chi-squared test. The curve with the lowest value will be the one with the best fit.

This curve can then be taken and slightly randomly modified to produce five new offspring. In their turn each of these can be tested to see if any of them are a closer fit than the original curve. The best can be taken and again be randomly modified to produce five more slightly different curves. With each new generation the value of the chi-squared statistic will come down; and the lower the chi-squared statistic the better approximation we have to the real *denarius* supply curve (as defined by the model).

Effectively this is a mathematical equivalent of natural selection. Here the fitness to survive being determined by the value of chi-squared. Those with the lowest values proceed to form the next generation of curves.

In the following section (3.5) this model is run and tested.

3.5 Testing the model

In order to use the model for the analysis of denarii in Britain we need the following information. First a representative sample of denarii deposited on British sites needs to be established (3.51). Secondly metrological and metallurgical details are required to establish a preferential recovery factor (3.52). Thirdly a routine for generating the model has to be established (3.53). And finally the results have to be compared with extant knowledge and tested to see if they bear any relation to reality (3.54 onwards).

3.51 *Denarius* site finds

The model developed in section 3.4 combines three sets of data to provide an idea of the changing volume of coinage in circulation. First the changing composition of the circulation pool, which can arguably be obtained by establishing the normal population of coin hoards over time (cf. Appendix 2.42). Secondly the changing intrinsic value of the coins themselves (should the choice to account for differential retrieval factors be exercised). For *denarii* , their silver content could be taken as an approximate guide (cf. Appendix 4.31). The third set of data required is a quantification of site finds.

The number of *denarii* deposited on the different site categories are provided in Appendix 3.51. Here genuine and fake *denarii* have been separated, with the number of copies being indicated in parenthesis... The proportion of genuine *denarii* found on different types of sites has also been graphically displayed in fig. 35.01.

The aim is to create a 'representative sample of the number of *denarii* lost on sites in Britain'. This is not as simple as it first seems. If any one type of site (eg. Roman towns) has a particular preponderance of, say, early silver, then problems of balance arise. How many of these kind of site are there in Britain compared with those of other types ? If Roman towns are over represented in our database then biases would creep into our overall picture. In an ideal world it would be nice to put together a series of coin lists from different types of sites in proportion to the number of such types of site in Britain. But in reality we are a long way off being able to say that in Britain there ten villas and twenty 'rural sites' for every Roman town. Regional variation would make a nonsense of such an attempt in any case. A second problem is that different coin lists have been accumulated in a wide variety of fashions. Few represent all the coins found on a site: excavations have usually only been on sample areas of sites and

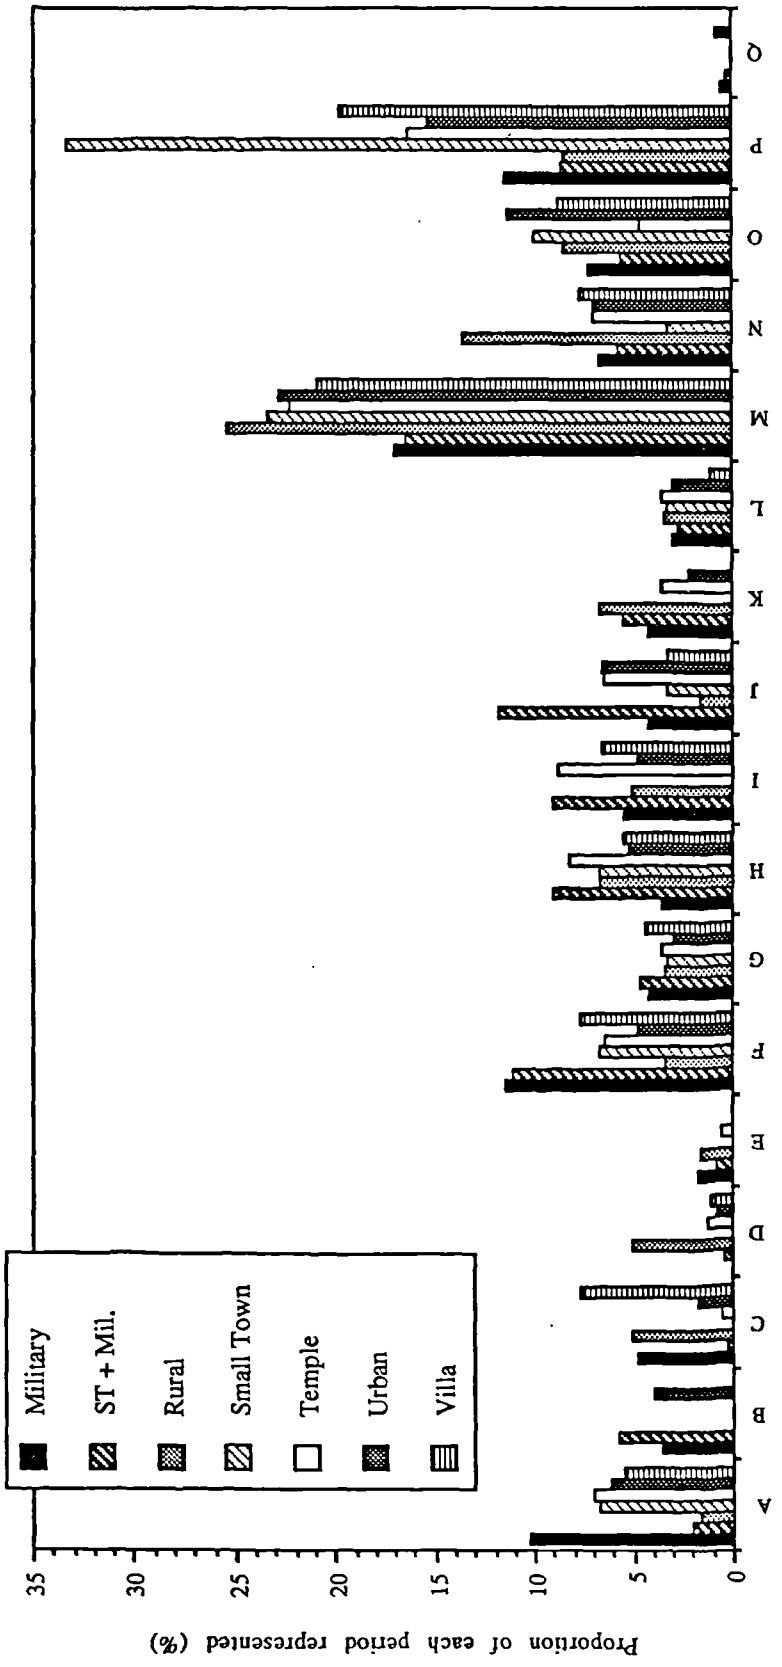

Fig. 35.01:
The proportion of *denarii* from different types of site in each period represented (%)

only recently has the use of metal detectors meant that anything approaching 'total recovery' has been reached.

In default of an ideal world not having come to pass, and since there is a broad similarity in the different proportions of *denarii* found on different types of sites in Britain (fig. 35.01), the decision has been made to take the simple option of lumping together all of the data together. for the time being. Though as the site corpus gradually increases in size different procedures may eventually become appropriate.

Table 3.51: *Denarii* from different types of site

		Forts	Small towns with forts	Rural	Small Towns	Temples	Public towns	Villas	Total Coins
A	Republican	17	17	1	2	12	14	5	68
B	Mark Antony	6	48	0	0	0	9	0	63
C	Julio-Claudian 1	8	2	3	0	1	4	7	25
D	Julio-Claudian 2	0	3	3	0	2	2	1	11
E	Civil War	3	7	1	0	1	0	0	12
F	Flavian 1	19	91	2	2	11	11	7	143
G	Flavian 2	7	38	2	1	6	7	4	65
H	Trajanic	6	75	4	2	14	12	5	118
I	Hadrianic	9	74	3	0	15	11	6	118
J	Antonine 1	7	97	1	1	11	15	3	135
K	Antonine 2	7	45	4	0	6	5	0	67
L	Antonine 3	5	23	2	1	6	7	1	45
M	Severan 1a	28	136	15	7	38	52	19	295
N	Severan 1b	11	48	8	1	12	16	7	103
O	Severan 2a	12	46	5	3	8	26	8	108
P	Severan 2b	19	71	5	10	28	35	18	186
Q	Severan 2c	1	2	0	0	0	2	0	5
	Total	165	823	59	30	171	228	91	1567

An amalgamation of all such *denarii* can be used as the input data for the model. Imitation *denarii* have been excluded for two reasons: first their fake status may have lead to them being deliberately discarded, which would cause biases in our data; secondly it will be interesting to see if the period(s) of copying coincide with shortages of genuine *denarii*; shortages which can only be detected by establishing the supply of genuine *denarii* alone in the first instance. However, it must be admitted that in some coin reports it is quite possible that some fake *denarii* have not been recognized. This point is returned to later in the section.

3.52 Preferential recovery adjustment

Two *denarius* supply curves are to be generated: one with and one without a factor to account for the possibility of the preferential recovery of higher value coin. The way this can be done has already been outlined in section 3.47. The proportion of site finds is adjusted by use of a variable based upon the intrinsic value of each coin. In the case of the *denarius* the most objective source for this is the weight of silver in each coin as established by Walker (1976, 1977, & 1978). The calculations are shown in Table 3.52. The original data are shown in column 2, and the adjusted values in column 5. If

preferential recovery was a factor in coin deposition, then we would expect more of the earlier *denarii* to have been recovered than the later ones due to the decline in the intrinsic value of the coin as the debasement took place. Hence the adjusted values for *denarius* deposition show enhanced values for early *denarii* whilst depressing the proportion of later coin represented.

Table 3.52: Correcting for preferential recovery
1. The number of *denarii* found as site finds (raw data).
2. The number of *denarii* found as site finds (%), this is SFn.
3. The weight of silver in each individual *denarius* (gms), this is Rn, see Appendix 4.51.
4. Column 1 x Column 3; using the weight of silver to act as a variable accounting for preferential recovery.
5. The adjusted proportion of *denarii* which may have been originally lost on sites (%), this is MSFn.
6. The difference between MSFn and SFn. Note the earlier higher silver *denarii* are now better represented, and the lower silver third century *denarii* are less well represented.

3.53 Calculating the money-supply curve

Section 3.53 has provided us with values for SF_n and MSF_n. In this section the *denarius*- supply curves are calculated in accordance with the procedure outlined in section 3.46. For there to be a 99.5 % level of significance in terms of the similarity between the ratios of the 'areas on the graphs' and the 'ratios of the SF_n and MSF_n values', the chi-squared statistic must be less than 4.60. In fact the generation of the curves has been allowed to continue until the values came below 1.0, however, with each further generation reductions in the chi-squared value were getting increasingly small and so the process was halted. In the case of Method 1 (no recovery factor) this was at a value of 0.996, whilst in the case of Method 2 (with recovery factor) this was 0.944. The calculation is shown in Table 3.53. The curves are shown in figs. 35.02 and 35.03. The data for the shape of each curve are given in Appendix 3.52.

Table 3.53: The closeness of fit of each curve (note: values only shown to two or three decimal places)

	Method 1 (no recovery factor)				Method 2 (with recovery factor)			
	% Area	% Site finds	Σ(f-fe)^2 fe	A-SFn	% Area	% Site finds	Σ(f-fe)^2/fe	A-MSFn
A+B	8.05	8.35	0.011	-0.31	11.76	11.86	0.001	-0.10
C	1.54	1.59	0.001	-0.05	2.33	2.41	0.002	-0.08

J	8.89	8.61	0.008	0.28	10.50	10.02	0.021	0.48
K	3.22	4.27	0.338	-1.05	3.53	4.68	0.376	-1.15
L	3.38	2.87	0.076	0.51	3.11	2.79	0.033	0.32
M	18.20	18.82	0.021	-0.62	14.11	15.18	0.080	-1.07
N	6.50	6.57	0.000	-0.07	5.15	4.66	0.048	0.49
O	8.26	6.89	0.228	1.38	5.25	4.41	0.132	0.84
P	10.97	11.86	0.073	-0.90	6.41	6.90	0.037	-0.49
Q	0.42	0.31	0.025	0.10	0.24	0.20	0.006	0.04
	100.00	100.00	**0.996**		100.00	100.00	**0.944**	
The data for the relative shape of each curve is given in Appendix 3.52. For the curves see figs. 35.02 & 03								

Degrees of freedom =	15	Chi squared statistic:			
Chi squared for METHOD 1 =	0.996	Quantile:	99.5%	95%	5%	0.5%
Chi squared for METHOD 2 =	0.944	Value:	24.99	32.80	7.26	4.60

The first thing to note is the high degree of similarity between the two curves. The main points of dissimilarity are in the relative size of the peaks in the 50s and 230s. This is largely to be expected. The major differences between SF_n and MSF_n (see Table 3.52) were in the proportion of Republican, Flavian and Severan *denarii* on sites. The curve including the recovery factor enhances the earlier values at the expense of the Severan peak.

The first thing to emphasise is that only the broad trends from the graph should be examined (i.e. those appearing in both graphs). These are:

1. The early peak in supply in the 40-50s.
2. The shortage of *denarii* up until the late first century, where upon they increase again.
3. A cessation in the growth in the 120s
4. A sharp increase in the numbers in circulation in the 170s.
5. A dramatic rise in the number in circulation in the 220-30s.
6. An equally dramatic decline in the numbers in circulation in the 240s, with no significant numbers continuing in circulation beyond the 250s.

Now this graph should be tested against other data at our disposal to see if it is consonant or not.

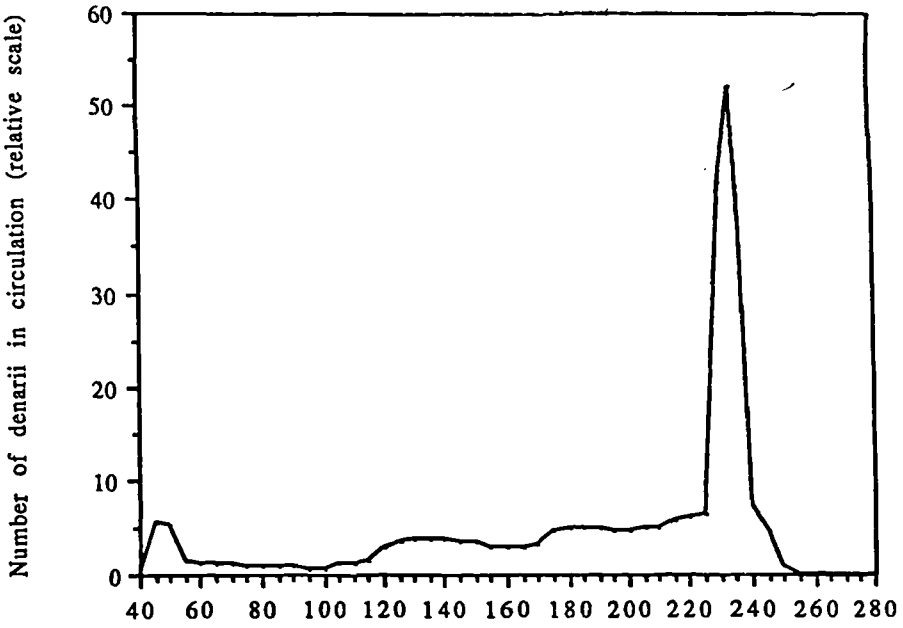

Fig. 35.02: *Denarius* supply curve: method 1 (no preferential recovery)

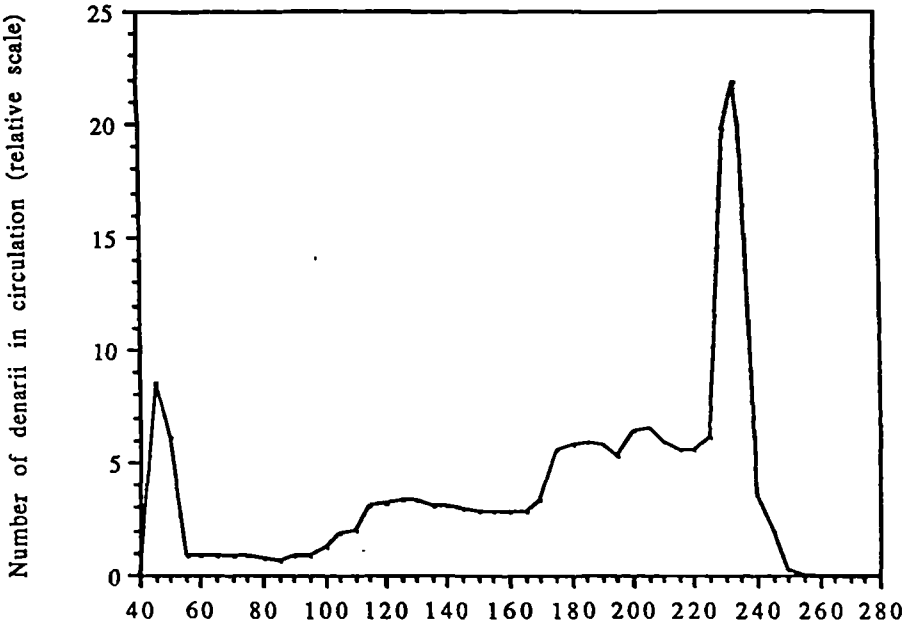

Fig. 35.03: *Denarius* supply curve: method 2 (preferential recovery)

3.54 Testing the model: Preliminary remarks

I expected a gradual increase in the number of *denarii* in circulation in Britain; reasonably gradual up until the Severan period when I expected it to rise rapidly, then decline as the *antoninianus* took over. The rationale behind this feeling was that as the *denarius* became baser, presumably there were more of them in circulation. This pattern is found, but with two important differences. First the Claudian peak, and secondly the step-wise growth in the volume of *denarii* in circulation - if the model is true that is. The task here is to test these curves against independent evidence to see if these trends can be borne out in reality.

The Claudian peak could be explained as a function of the huge degree of military activity in Britain in the early period, however, if that were the only explanation then one would have expected it to have been sustained for a little bit longer. Nor can the large number of allegedly Boudican hoards (contested in section 4.1) be used to explain away the peak. First the peak is too early, ending around the time of the Boudican revolt, and secondly the curve does not represent the number of hoards or even the size of them. It represents the total number of coins thought to be in circulation. A sudden peak in the number of hoards recovered in modern times will have no effect upon the shape of this curve. However, the end of the peak might possibly reflect the calling in of loans to the native elite:

> "Claudius had given sums of money to the leading Britons, and according to Catus Decianus, the procurator of the island, this money had to be returned together with the rest. The confiscation of this money was the pretext for the war. In addition, Seneca, with a view to a good rate of interest, had lent the reluctant islanders 40,000,000 HS and had then called it all in at once, and not very gently. So rebellion broke out."
>
> (Dio 62, 2, 1)

If the loans took the form of cash, then this would certainly fit the date. Another reason for an early peak would be the replacement of the native Iron Age coins with Roman *denarii*. Though we do not know this took place, the Roman state must have had some interest in the metal reserve tied up in these Iron Age coins.

However, none of this is really a test of the data, it is more in the nature of an *interpretation* trying to explain away the pattern. First I want to examine some other phenomenon which are reasonably independent of historical interpretation, before moving back to put the graph into its historical context.

3.55 Testing the model: Hoard size

The radical changes in the number of *denarii* in circulation over the first and second century must have affected how much coin was available for people to hoard. If there were 100 people in a group with money-boxes, and the amount of money in circulation suddenly halved, either half the people hoarding money would have to stop it, or else the median size of coin hoards would have to come down by half. This seems to be a reasonable working hypothesis. Hoard size was examined back in section 2.6, and the median hoard sizes were calculated in 20 year blocks (see fig. 26.04).

The pattern reflected there was of a high median figure to start with in the 40-50s, followed by a cut to about quarter of the value in the 60-70s. The position is partly re-established in the early second century. A further substantial rise can be found between the 160-170s and 180-190s. These coincide with the *denarius* supply curves. This evidence provides support for the early decline in the number of *denarii* in circulation, its gradual rise again, and possibly of a step up in numbers around 180. It should be stressed that the model is based upon the structure of hoards, site finds and the silver content of *denarii* . At no point does information pertaining to the size or number of coin hoards enter into the creation of the curve, therefore this is totally independent corroboration.

3.56 Testing the model: Imitating denarii

It is a numismatic truism that copying takes place when coinage is going into short supply and the type of coin copied is the last issue present in any quantity. Such was the case with the barbarous radiates of the late third century and the *Fel Temp* copies of the fourth century. When copying did not take place it was conspicuous by its absence, for example at the end of Roman Britain when new supplies of coin from the empire finally ended. Is there any evidence that *denarii* were copied at the two dates when our graph suggests it was rapidly disappearing from circulation? The second period is the easiest to deal with. Large numbers of Severan copies, more often than not plated, are found. It will be shown later (Chapter 4.7 - The *denarius* to *antoninianus* transition) that the types copied match precisely those in circulation in the late 230s. Archaeological evidence is also cited which shows that this period of copying continued for a bit longer after that. However, the details will not be pre-empted here. Suffice it to say that there is substantial evidence for the copying of *denarii* in the late 230-240s.

The plated *denarii* of the early third century make up the vast majority of irregular *denarii* in Britain. Very few earlier finds have been made. Two of the three Claudian *denarii* in the site find database (Appendix 3.51) are copies, and a Tiberian copy is

known from Swanton Morley in Norfolk (Kenyon, MS 1). Another Tiberian copy is known from the Llanfaethlu hoard, Anglesey (C151n). It is unlikely that these were copied during the early third century, since virtually no *denarii* of this date were still in circulation then. However, the most curious find is one dating to the late Claudian period in London, the hoard from St. Swithin's Lane. This was a find of several hundred plated *denarii* from Mark Antony to Claudius. It has always been difficult to explain:

> "Haverfield suggested that in these coins we should recognize the ancient equivalent of the modern paper currencies, designed for the convenience of the invading legions of Claudius. But this theory has many objections, not least being the doubt whether, at this stage of imperial history, an emperor would dare pay his troops in base currency."
>
> (Sutherland 1937, 9)

However, if we view the forgeries in the context of a late Claudian decline in the number of *denarii* in circulation it makes more sense. Since no coins of Nero are represented we can give it a T.P.Q. of 41-54, our analysis of the structure of the hoard (Appendix 2.53) suggested it would be later rather than earlier, suggesting 54 onwards on the basis of comparison with our bench-mark, though for this date the bench-mark relies upon few examples. The decline takes place on both graphs some where between 50 and 55. It is quite possible that the hoard dates to the period of *denarius* withdrawal or very shortly thereafter.

If there was much copying at this date, and St. Swithin's Lane is not an isolated example, then the absence of Neronian copies (Sutherland 1937, 10) suggests it was very short lived, i.e. it didn't continue into his reign; or conversely that there were not enough of his *denarii* around at that stage to copy.

From the St Swithin's hoard and the site find copies we have evidence which is not inconsistent with the idea of a rapidly declining number of *denarii* in Britain in the late years of Claudius' reign (or the very early years of Nero).

3.57 Interpreting the results: Sudden rises in the supply curve

At several points the curves suddenly rise up. Apart from the initial invasion, these are at the following dates: c. AD 120, 175 and 230. Did anything in particular happen during these dates in Britain?

AD 120 is very close to the visit of the Emperor Hadrian to the country in 121 or 122 and the arrival of the Legio VI from Germany (probably c. 122 from Lower Germany, though it is difficult to prove it arrived in York earlier than 130). Whist there was much military activity with the construction of Hadrian's Wall, I think that almost any date

from the Claudian conquest to the late second century could identify military activity as a reason for extra money coming into the country. However, the presence of the Emperor himself is a much more convincing explanation. Many activities have been related to Hadrian's visit: the draining of the Fens, the construction of the *Tholos* at Bath (Cunliffe 1986) and many other developments in towns throughout the province (cf. Salway 1984, 185-5). Whether these constructions were due to direct Imperial patronage or local collective effort - they coincide with the first significant rise in the number of *denarii* around since the initial Claudian peak (which incidentally followed an earlier imperial visit).

AD 175 again saw a significant rise in the number of coins present. However, there were no imperial visits then. There were various phases of garrison rebuilding in the north during Marcus Aurelius' reign, the Wroxeter forum was burnt down and 5,500 cavalry from the Iazyges came to Britain (Dio, 71, 16, 2); but apart from that no obvious causes for such a rise can be detected.

Clodius Albinus was the next Emperor to be found in Britain, however, since he was proclaimed here as opposed to visiting the country it is most unlikely that he would have brought any additional resources with him. No increase is found in the record upon his accession (192-196 in Britain, defeated in Gaul 197).

The next imperial visit came in 208 with Septimius Severus, who unfortunately died here in 211. No obvious sign of his presence is recorded in the quantity of *denarii* suggested in the province by this model. This is despite his increase in army pay from Domitian's 300 *denarii* to 400. Caracalla raised it again shortly thereafter to 600, but again this does not appear to be reflected in the curve - but then one wonders how much of the pay the army ever actually saw in the form of hard cash. Much appears to have been stopped for food, equipment, burial clubs and savings schemes (cf. section 4.52). The model also fails to register the 'great treasure' Herodian tells us Septimius Severus brought to Britain.

AD 230 is the next date where a large increase took place. Nothing obviously took place at this date.

3.58 Testing the models: The Antonine Wall

> "Will we ever understand the strategy of the curious backwards and forwards movements between Hadrian's Wall and the Antonine Wall in the years AD 122-164 ?"
>
> (Whittaker, 1989, 64)

In an ideal world the Antonine wall would provide us with an excellent possibility of testing our curve. If the Wall was occupied from date X to date Y then we could predict

the number of *denarii* we might expect to find there. However, the dates of the Antonine Wall are a rather contentious matter. Breeze (1989) tried to summarize the state of present knowledge, but even so the picture is remarkably confused.

The move forward from Hadrian's Wall under the governor Lollius Urbicus came in either 139 or 140-144 (depending upon the consular dates on the damaged part of an inscribed milestone from Ingliston - Breeze 1989, 46). In 142/3 coins announced a victory in Britain, and the *Scriptores Historia Augustae* tells us that having driven off the barbarians another wall of turf was built. Thereafter it was abandoned for a short while before being reoccupied again. The break came in the mid-150s (Macdonald), 158-184 (Hadrian's Wall chronology), or the mid 160s (Hartley) depending upon which author you accept. Hartley's date based upon a reassessment of the samian ware on both the Antonine Wall and Hadrian's Wall has the greatest currency at the moment. The final abandonment of the Wall is an equally movable feast. Coins (*aes* as well as *denarii*) of Marcus Aurelius and Commodus are very rare from the wall. In fact only one of Commodus is known (Robertson 1971, 133), making it most unlikely that the second occupation lasted much beyond the start of Commodus' reign in 177 or when he became Caesar in 175.

What we can do with the *denarii* from the Antonine wall is try to fit a curve to them as we did with our site find list for the country as a whole. If it gives us two peaks, one in the 140s and a second later one ending in the 170s this might provide some additional validation for the model - if not for the overall *denarius* supply curve itself.

Instead of making up curves with five year time slices, one year time slices can be produced by interpolation. However, this is not to suggest an increased level of accuracy which has not altered in any way. The original *denarii* in the database are still only dated to an Emperor's reign - so we should not expect too great a resolution from this analysis. The results of three curves are given (along with their chi-squared statistic) in fig. 35.04. These represent various generations *en route* to the final curve which is shown alone in fig. 35.05. The results show an initial peak in the late 120s and early 130s, followed by a lower level secondary occupation in the late 160s to early 170s. The fact that the model has been able to suggest that the coins from the wall come from two distinct phases is encouraging. The first phase, however, has been dated approximately a decade too early. The date for the secondary occupation of the wall is quite plausible. Indeed its termination around 177 fits in well with the paucity of finds of Commodus and Crispina from sites.

Broadly the model has managed to demonstrate that the Antonine Wall did have two phases of occupation/coin deposition - simply from analysing its *denarius* site find list.

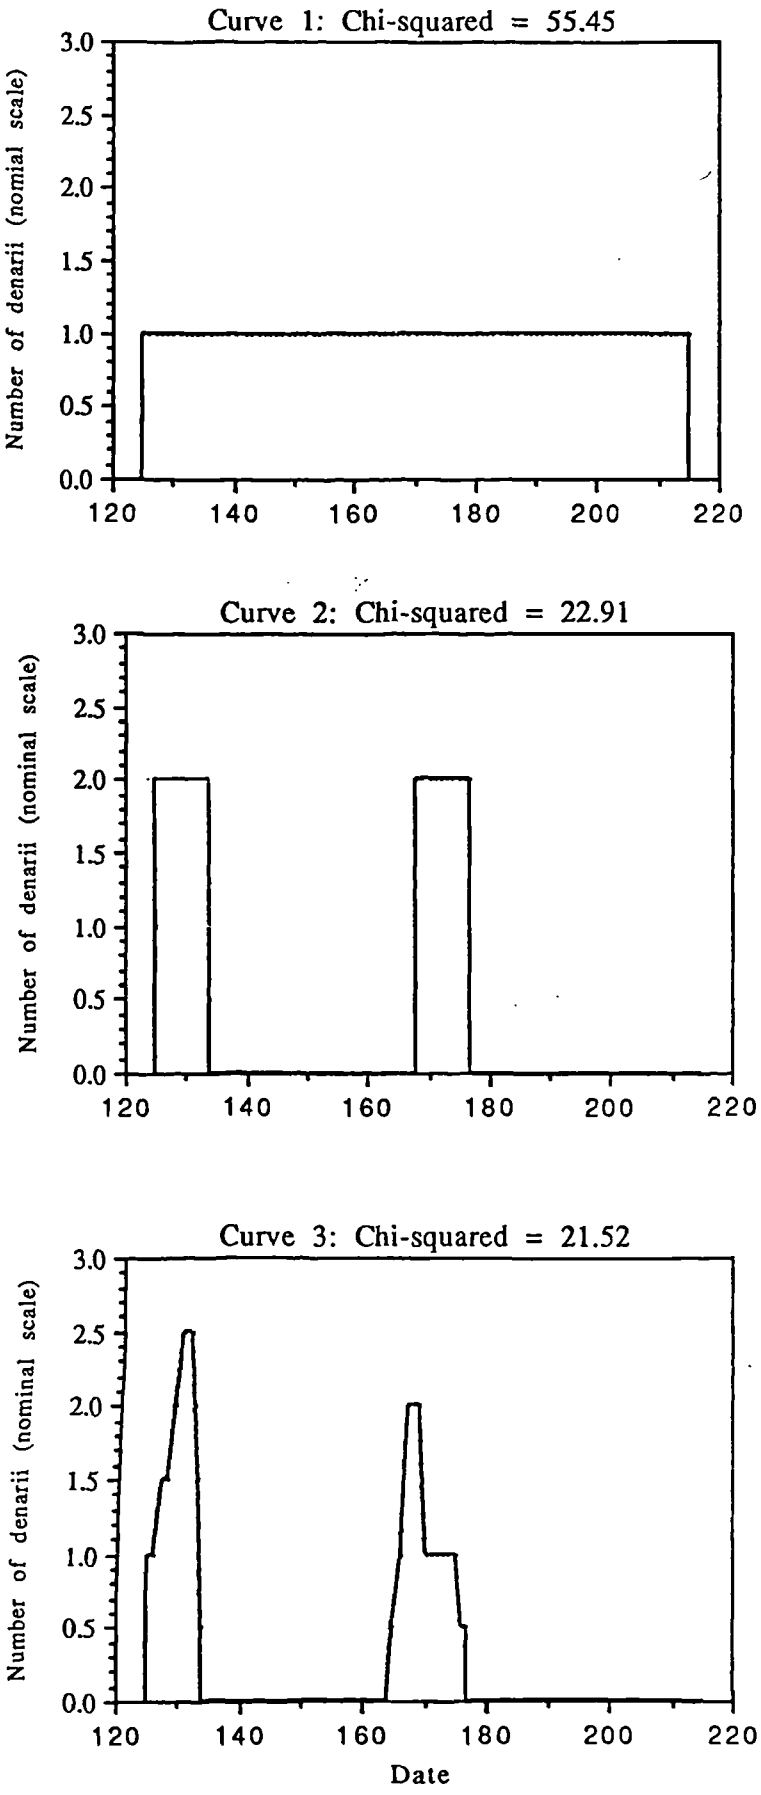

Fig. 35.04: Antonine Wall: *denarius* supply curve (3 generations)

Its dating of the phases of occupation is crude (but then so is the dating of the *denarii* to merely Emperor's reigns), but suggests that the technique does have some kind of validity.

Table 3.54: Antonine Wall *denarii* and the model predictions.

AD130	2.5	AD170	1.0
AD131	2.5	AD171	1.0
AD132	2.0	AD172	1.0
AD133	1.5	AD173	1.0
AD134	0.5	AD174	1.0
		AD175	1.0
		AD176	0.5
		AD177	0.5

3.59 Conclusion

Whilst the shape of the *denarius* supply curve was not expected, on reflection it does stand up to some measure of scrutiny. The size of coin hoards provides some independent corroboration as to the general shape. The analysis of the coins from the Antonine Wall provides some validity to the method; and independent historical information has been able to suggest causes for some (though by no means all) of the changes in the shape of the curve.

Section 4: Thematic Studies and Synthesis

4.1 Iron Age to Roman transition

After an introduction to Iron Age coinage, the specific case of the Iceni is examined. On the basis of this further regional trends are sought determining how much LPRIA monetary history influenced the uptake of Roman coinage. Following this the early stages of the Roman system are examined, concentrating particularly upon the production of Claudian copies. It is concluded that many of the trends seen in LPRIA Britain persist under the guise of the new Roman system.

4.2 The circulation of bronze and silver

The relationship between the bronze and silver circulation systems is discussed. First Walker's Bath coin report is examined to evaluate his estimates of the number of bronze coins in circulation in Britain (4.21). Secondly an attempt is made to derive *aes* supply figures as done previously for *denarii*.. This is achieved with *sestertii*. (4.22). A second method for reconstructing Bronze supply figures is then described based on wastage rates. The results are not dissimilar to those from the previous model (4.23). The results are then assessed in the light of the *denarius* data and other information about the circulation of both silver and bronze coin (4.24-25).

4.3. The debasement of the *denarius*

Prevailing views of the concept of debasement are discussed (4.31). A study then relates the amount of silver circulating in the currency pool to the issuing standard at the mint (4.32-33). Variability in the quality of newly issued *denarii* is discussed in relation to bullion supplies and quality control (4.34), finally a primary link between the rate of wear of the *denarius* in circulation and its debasement is made (4.35).

4.4 The *denarius* to *antoninianus* transition

In c. 215 the '*antoninianus*' was introduced. By 244 the *denarius* had ceased to be issued as a regular part of the currency. This section examines some of the associated events. First the evidence of *denarius* imitations is assessed (4.41), then the pattern of hoards and site finds is examined to see what light they throw upon the subject (4.42).

4.5 The quantity theory of money and cyclical trends in the economy

The quantity theory of money is introduced, relating the variables of money supply, velocity of circulation, prices and the quantity of goods and services being transacted within the monetary economy (Y) (4.51). Three of these variables are then established (4.52-54) leaving only Y unknown, this is then established (4.55). The variations in Y are then related to archaeological evidence (4.56) and to broader changes in the economy of the Empire (4.57-8).

4.1 Iron Age to Roman transition

This section examines the transition from the Iron Age to Roman monetary system. After an introduction to Iron Age coinage, the specific case of the Iceni is examined. On the basis of this further regional trends are sought determining how much LPRIA monetary history influenced the uptake of Roman coinage. Following this the early stages of the Roman system are examined, concentrating particularly upon the production of Claudian copies. It is concluded that many of the trends seen in LPRIA Britain persist under the guise of the new Roman system.

4.11 Introduction

The arrival of Roman coin in 43 was not Britain's first experience of coinage. Indigenous systems had developed to different degrees over the previous century or more. Development speeded up in the post-Caesarean period when not only was inscribed coin minted, but some areas also started producing bronze coinage. Before examining the transition from the native to Roman currency system itself two questions must be addressed. First, as far as we can tell, how was Iron Age coinage used? Secondly, what stage had it reached in the different areas upon the conquest?

> "...the primary role of coinage was probably in the vertical relationships between issuers and their subordinates in its territory of origin, its use in horizontal relationships between individuals and groups was essentially a characteristic acquired through circulation, rather than the reason for its issue."
>
> (Haselgrove 1987, 212)

Haselgrove distinguishes between the reason for issuing coin and its subsequent function. Such a differentiation is also common to analyses of Roman coinage: Crawford linked the issue of Republican *denarii* explicitly to the demands of the military (Crawford 1974), what happened thereafter to the coin was not the concern of the state. Extremely old worn Republican issues were to circulate quite happily amongst later issues for over a century or more (though see section 4.3). Where differences in the interpretation of Iron Age and Roman systems most obviously occur is that with Iron Age coinage it is commonly accepted that different types of coin had different roles within society; whereas Roman coinage is rarely perceived as anything other than a fully integrated denominational system. For Iron Age coins functional specificity is emphasised. Gold, silver, potin and bronze all had at various times different depositional patterns. One good expression of this type of interpretation is

Haselgrove's description of the coinage of South East Britain in the late pre-conquest period:

> "In being restricted to the core territories of (by then) comparatively centralised polities..., the South-Eastern silver and bronze and Southern silver have very much the character of Dalton's (1977) *early cash*, contrasting with the continued export of gold to the outlying areas throughout Period III. ... If these gold distributions are indicative of political dependence ... it may well be that the same is true of the earlier potin distributions, i.e. that potin was initially a form of *primitive valuable*..., and was accumulated and transacted in non-commercial ways, such as alliance formation or tribute payments between different areas linked in some form of wider grouping, and the discharge of social obligations within them."
> (Haselgrove 1987, 159-60; my italics)

Here the role of gold and early potin is distinguished from silver and bronze. The picture given is decidedly dynamic and the use of coin could change rapidly. In the late pre-conquest period bronze coin was slightly more common on nucleated settlements. However, after the conquest the same coin starts appearing on sites where it had failed to register before, namely production sites such as the saltings and kiln sites along the north Kent coast; sites where previously only gold and potin were found (Haselgrove 1987, 157). The role of potin itself appears to have changed, from an early similarity to the use of gold, to a distribution more akin to that of bronze in the later period occasionally liked to the concept of incipient market development (cf. Allen 1971, Kent 1978). Interpretations can (and do) vary.

It is not the aim here to list the different functions of each type of coin at each date. That would not be possible. The important thing to emphasise is that with Late Pre-Roman Iron Age (hereafter LPRIA) coinage the idea that different types of coin fulfilled different social needs is the established viewpoint, though the details may differ.

The next stage is to assess the different levels of development of the LPRIA currencies in each region. The starting point for this is Haselgrove's analysis of Iron Age coin (1987). Here the issues have been divided up into regional groups (fig. 41.01). The peripheral groups can broadly be linked to the Iron Age territories of the Iceni (East Anglian series), Corieltauvi (North Eastern Series), Dobunni (Western series) and Durotriges (South Western series). The core circulation areas are divided into the Southern, South Eastern and Eastern series. Throughout I have tried to avoid using tribal names in association with the core provinces in particular. It is difficult to tell precisely how relevant the later Roman creation and boundaries of the civitates are to the LPRIA social and political geography (relevant: Millett 1990, not quite so relevant: Haselgrove 1984).

Some of these regions had a full range of gold, silver and bronze coins in circulation. The words gold, silver and bronze are used here very loosely, since metallurgical analysis has made us aware that the alloy composition of each series was in a tremendous state of flux, though apparently under strict control nonetheless (cf. Van Arsdell 1989, 501). Other regions had only gold and silver in circulation. The rest had no coinage at all. The information is summarised in fig. 41.01. An idea of the types of coin being produced in the final three periods of Iron Age coin production is given in Table 4.11.

Table 4.11: The denominational structure of each LPRIA system in periods 7-9.
The data are derived from Haselgrove (1987). The numbers represent the number of Mack entries in each series. This gives a broad idea of the number of types and their spread across the denominations. However, it should be noted that there are several biases in this picture. First some series are divided into more types than others owing to finer divisions rather than to there actually being more variation in the series. Secondly, no indication is given of the number of dies per type, and this may have varied greatly. Thirdly, the number of coins struck per die may have varied. Excluded from this table are the potin coins and the thin silver series.

	GOLD		SILVER				COPPER ALLOY		
	AV	AV 1/4	AR	AR 1/2	AR 1/4	AE/AR	AE2	AE	AE 1/2
E7	10	7	13				1	20	5
E8	9	5	21				1	31	1
SE7	8	7	8					11	1
SE8	2	4	6		1			4	1
SW7			1		1				
SW8						1		1	
SW9								1	
S7	5	7	3		3				
S8	4	8	6		7				
S9	1		4		4				
EA7	4	1	9	1					
EA8	1		5	1					
EA9			11	3					
NE7	5		4	5	1				
NE8	5		4	3					
NE9	3		4	4					
W7			5						
W8	3	1	2						
W9	5	1	4						

The principle distinction to be drawn is between the precious metal peripheral systems (EA, NE, W, S and possibly SW) and the bronze using core (E and SE). In the final stages of the LPRIA this division also correlates with another, the difference between open and closed currency areas. Coinage of the Iceni is infrequently found outside Icenian territory, likewise extraneous coins are uncommonly found inside Icenian territory. This part of East Anglia can therefore be seen as a closed circulation area in the LPRIA. In order for there to have been any transactions between outside interests and the Iceni, coin first had to be changed. Closed systems provide easier means of control over inter regional exchange. A similar pattern applies, more or less, to the other peripheral areas, though perhaps less so for the southern series. In the core however such discrete circulation areas are harder to find. Varieties of coin were

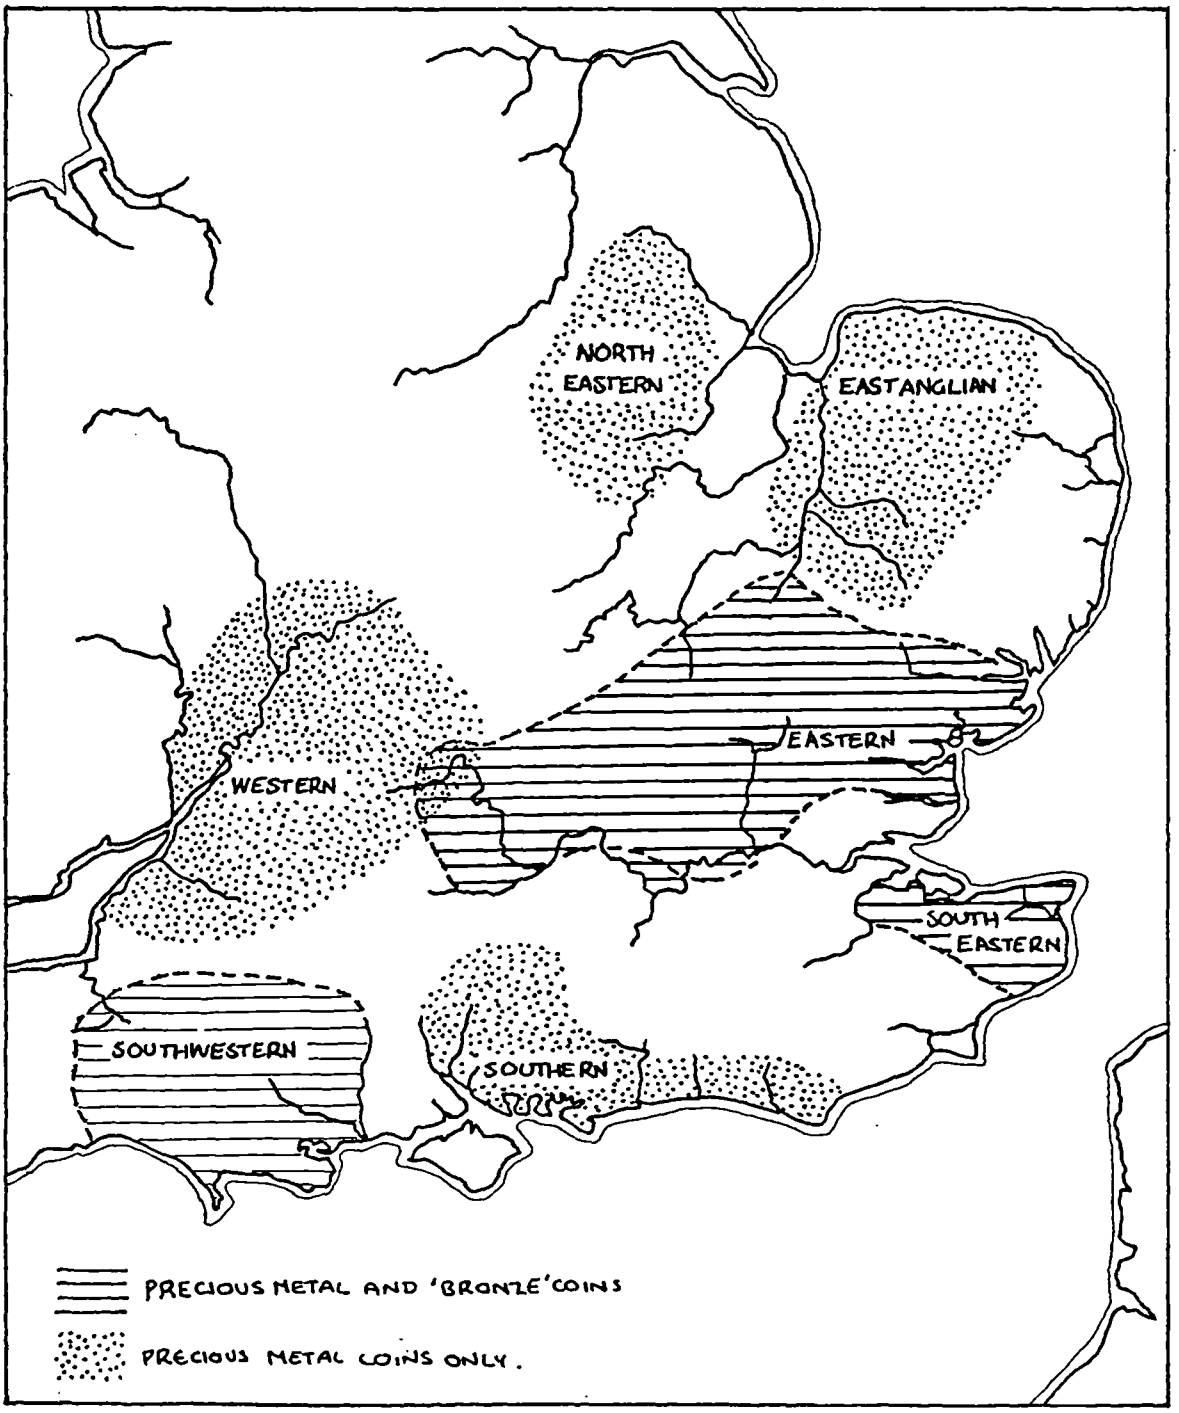

Fig. 41.01 LPRIA Coin Zones and denominational systems.

acceptable at different dates in different places (cf Cunliffe 1981). The fluidity of coin exchange between areas in the core therefore suggests less regulated control over inter-regional exchange than a closed system would suggest.

In the forthcoming analysis we must take into account the following ideas and questions. First, different denominations in the LPRIA are perceived as having different social functions, if this is the case was the multi-denominational Roman coinage system used in a similar way, at least initially ? Secondly the different levels of denominational development in the regions may have a similar effect upon the uptake and use of different Roman denominations. Would an area unused to using bronze coin accept it as readily as one which had been producing it indigenously before the conquest? Thirdly, can we detect any differences in the response of the LPRIA open and closed currency areas to Roman coin in the early period?

4.12 Icenian hoard evidence

The Iceni of East Anglia provide one area where this transition can be looked at in detail. Hoards containing both Icenian and Roman coins are known from here, what can they tell us?

More than a dozen late Icenian silver hoards have been discovered. The temptation to link them to the historical events of the invasion or the revolts of 47 and 60/1 has been irresistible (Eg. Rainbird Clarke 1956; Allen 1970; Van Arsdell 1987), though it has been the last which has found the greatest favour. However, only two of the hoards necessarily warrant such late a date as the Boudican revolt: the Scole and Joist Fen hoards. The Scole hoard (Burnett 1986) contained a *denarius* of Nero (BMC 24) dating to AD 60/1; similarly the Joist Fen hoard contained one of c.AD 55-60 (Briscoe 1963). Otherwise those which do contain Roman coins end with earlier issues whose terminal dates range from the Republic to the beginning of Nero's reign (Table 4.12). Of course this does not necessarily preclude them all from being Boudican deposits (the Roman coins only provide *termini post quem* after all), but the dating has implications regarding the chronology of the final Icenian issues, particularly the question as to whether any were minted after the Claudian conquest. Van Arsdell has suggested an extremely late chronology, dating one large issue to the Boudican revolt itself [this issue being Van Arsdell's Icenian O, Mack's 413 & 413d, Allen's IIIb-c or Haselgrove's 73.2 & 83.1 depending which classification one wishes to use] (Van Arsdell 1987). This argument rests upon the heavy weight of the coins compared with his theoretical issue weight for them, implying that the examples in the hoards were almost unworn. This is a theoretical conclusion which is directly contradicted by

Allen's observations of the coinage, where he describes the IIIb coins as being 'noticeably more worn' than other Face-Horse coins (Allen 1970, 28).

Table 4.12: The latest Roman coins in each hoard

Weston Longville	Republican	Roach Smith (1853) & Carradice (1989)
Chatteris	Tiberius ?	Burnett (1986)
Lakenheath	Caligula, AD 37/41	Briscoe et al (1958)
Santon Downham	Claudius, c. AD 43/54	Allen (1970). These were copied asses
Eriswell	Nero, AD 54/55	Kent & Burnett (1984)
Joist Fen	Nero, AD 55/60	Briscoe (1963)
Scole	Nero, AD 60/61	Burnett (1986)

If we start from a different premise, that the hoards represent a series of deposits at different dates, the conclusions resulting are very different to Van Arsdell's. Since all the late hoards contain the 'Icenian O' coins which he ascribes to Boudica, if any one hoard is demonstrably earlier, his late chronology becomes untenable. Similarly since all the hoards contain virtually the same range of coin, none of these issues could have been minted before the date of the earliest hoard (with the exclusion of the SUBRIPRASTO issue which is only found in one, to which we will return later). Therefore before we go any further it would be wise to see if there is any evidence for the hoards representing a chronological series, rather than a group all deposited at once. So let us free ourselves for a moment from the historical framework of the Icenian revolts and examine the coin hoards in their own right.

The chronological ordering of the coins comes from three sources: first stylistic affiliations, secondly the relative state of wear of the coins in hoards and thirdly the 'number of coins per obverse die' figures for each issue in the late hoards (the longer a coin series has been in circulation, the fewer examples of each die one expects to find). There is a large measure of agreement about the relative chronology of the series between those who have examined it, the principle works being Allen's original study (Allen 1970) and Haselgrove's review and periodization of the coins of the South East (Haselgrove 1987). The important thing to note is that neither drew upon differences in the structure of the late hoards to form their chronologies. This discounts the possibility of there being any circularity in the analysis that follows.

In order to examine the chronological trends in the patterning of hoards, the starting point would be a seriation; ordering them in terms of those hoards with the highest proportion of old coins to those with the highest proportion of new issues. This has been done in fig. 41.02 (hoards not referred to so far: Wimblington, March, Honingham, see Allen 1970). In sequence the hoards show a straightforward progression. The hoards to the left contain a higher proportions of coin of periods 6 (EA62) and 7 (EA71.1, 72.1-3, 73.1-2), whilst only the Joist Fen hoard on the far right that contains the latest type in phase 9 (EA94). The classification used is Haselgrove's with Allen's

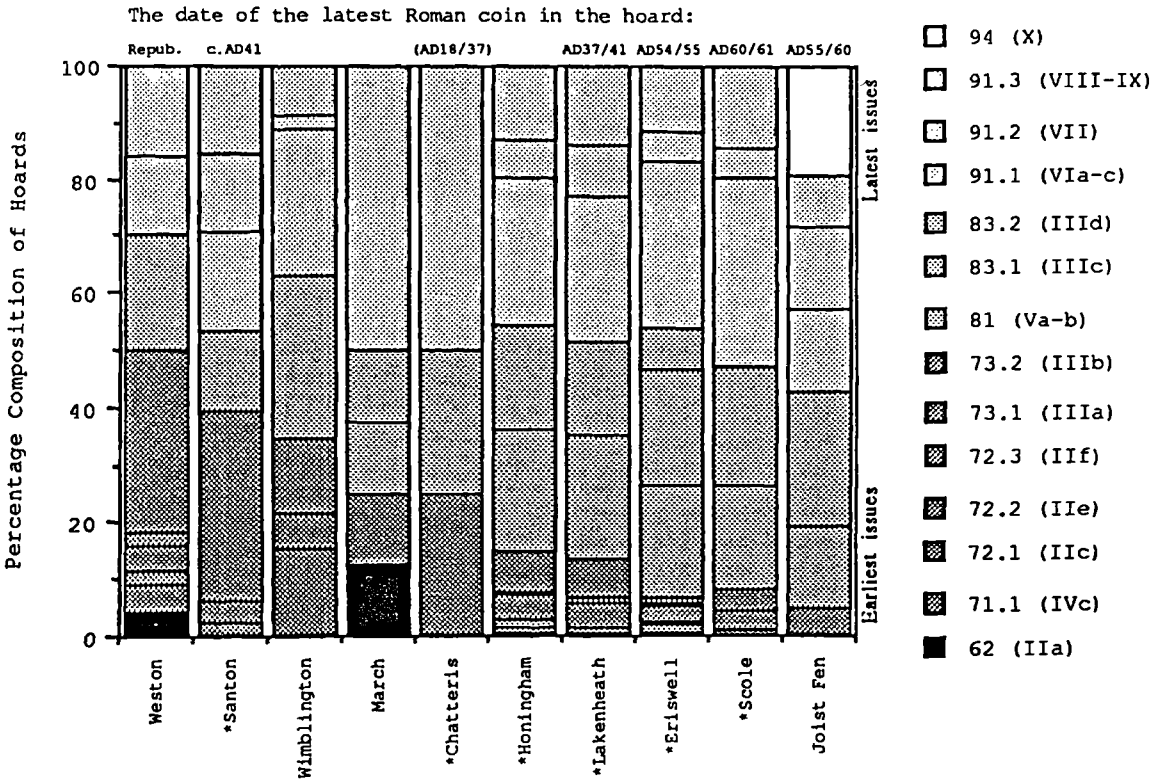

Fig. 41.02 The Icenian coin hoards.

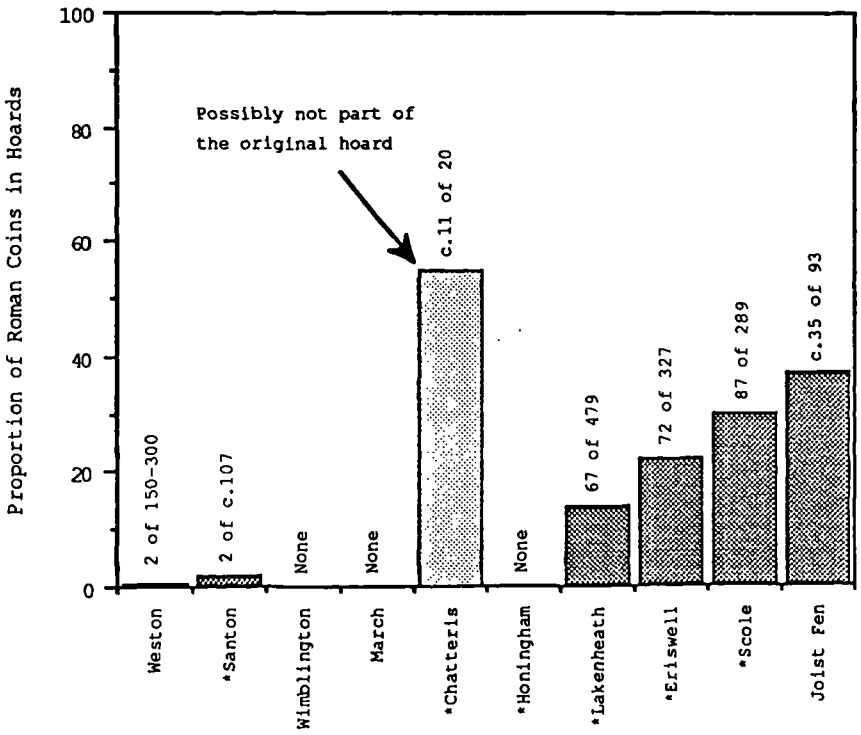

Fig. 41.03 The proportion of Roman coins in Icenian coin hoards.

given in brackets. Of course the quality of the data used must not be overlooked. Those hoards with an asterisk by them were represented by a high quality of data, whilst those without are known from only a proportion of the original hoard, or else the original description of the coins only allows for an approximate identification to be made. Now we have the hoards in a structural sequence, can we establish whether this pattern is due to a chronological change.

Our control comes from the presence of Roman coins. Do these coins with their varying terminal dates relate to the sequence proposed in fig. 41.02 ? If anything they confirm it. The hoards with the highest proportion of the latest Icenian issues (Scole and Joist Fen) contained the latest Roman coins. As one moves left along the chart the dates get earlier, until all are Claudian or pre-conquest (Note: the coin of AD 18/37 in the Chatteris hoard may be intrusive, this is discussed later).

Both the internal changing structure of the hoards and the terminal dates of the Roman coins contained within them tend to suggest that we are dealing with a chronological sequence of hoards, rather than a series deposited at one time. As stated above, this casts doubt upon the dating of any of the coin issues to late in the period of the client kingdom, or indeed to any time after 43 if the structurally earliest hoard (Weston) is as early as this; though by the nature of the evidence it is impossible to be certain. The exception to this is the SVBRIPRASTO issue (Haselgrove EA94, Allen X) which only appears in the latest hoard. This type of coin is only known from this single hoard and this one site. Therefore, it is quite than possible that this isolated issue *may* date to the final years of the client kingdom.

If we accept that these hoards do represent a chronological series then can this reveal anything to us about the nature of the transition here from the one monetary system to the other? Both types of coin were hoarded and mixed together, therefore it is difficult to conceive of them serving totally different social and economic functions. Was this mixing of systems a feature right from the first arrival of Roman coin into the area, or did the two forms of coin remain separate for a while, and only gradually merge? One way to examine the question would be to look at the proportion of Roman to Icenian coins in the hoards throughout the sequence (fig. 41.03). Though a trace of Roman coins can be found right from the first hoard, it is only in the later hoards that their proportion becomes at all significant. Only one exception to the trend is found: Chatteris. However, in this particular case the Roman coins may not in fact have been part of the Iron Age hoard at all. 14 Roman (from the Republic to Domitian) and 9 Icenian coins were found, as Burnett writes:

> "[the] 23 coins seem to represent one or more hoards, but it is not clear exactly how these hoards should be defined. One might have expected that the Icenian and Roman silver from the Republic to Tiberius represented a hoard (cf. the Scole hoard), but the finder gave evidence that the Celtic coins were not found with the Roman. Nor is it entirely satisfactory to think of an imperial silver hoard ranging from the Republic to Domitian, since all the Tiberian denarii were in quite good condition, while the coin of Nero was well worn and that of Vitellius worn. One can only point to two nuclei, one of Icenian silver, and one of Roman silver (Republic to Tiberius), and leave as uncertain how many or which other coins may have belonged to them."
> (Burnett 1986)

In conclusion I believe the hoards represent a series of deposits concealed at a series of dates from the conquest or sometime thereafter to the Boudican revolt or shortly thereafter. If one wishes they can be seen as dating to the historical events of 43, 47 and 60/1 though this does not particularly matter. Throughout this period the hoarding of Roman coins alongside Icenian coins became more and more common. The attraction of Roman *denarii* over the local series may have lain in their heavier weight (the Roman *denarii* were about three times heavier) and their better quality of silver. The gradual displacement of Icenian coins by Roman ones can be seen as happening by default, rather than any act of deliberate policy. Whereas in the LPRIA Icenian coins rarely passed outside into other circulation areas, the mobility and growing acceptability of Roman silver in East Anglia immediately points to a difference in the nature of the relationship between Rome and the Iceni rather than, say, between the Iceni and its earlier neighbours to the south, whose coin it had not accepted. From a closed currency system in the LPRIA, the Iceni had over a generation opened up to accept this new form of coin which finally surpassed it.

If the hoard sequence does start as early as 43, as I believe it does, this means that the Iceni do not appear to have minted any coins except perhaps the SVBRIPRASTO issue during their period as a client kingdom. This need not mean that they did not have the right to (cf. Braund 1984, 123-8); though it appears that with this one possible exception, if they did have that right, they did not act on it. Apart from the evidence above for an early chronology, such an interpretation is backed up by Kent and Burnett's observation of the coins in the Eriswell hoard (Kent & Burnett 1984): "The condition of the latest Icenian coins in the hoard is worse that that of the latest Roman [*denarii*], and suggests that the minting of Icenian Silver ceased well before 60, perhaps even in 43."

In this light perhaps this final issue can be reconsidered. The coin itself is probably based on a Neronian prototype rather than following the earlier Icenian styles (Allen 1976; Mossop 1979; though R. Kenyon has suggested an alternative Tiberian prototype, pers. com.). The legend itself has been taken to read SVB RI PRASTO / Under King

Prasutagus, which is exceptional. Neither is it a full weight Icenian coin, but rather a fraction, weighing c. 0.7 g against the unit weight of about 1.2 g (Haselgrove 198-, 263; though it has been noted in Van Arsdell (1989, 212) that most of the recorded examples are chipped, and therefore a heavier original weight is probably warranted). The coin stands quite apart from the main Icenian series. Since as yet they have only been found at Joist Fen, they do not appear to have had much currency. Perhaps it can best be seen not as a main stream issue, but as a 'one-off' ceremonial issue. It might even relate to the accession of Prasutagus, if as some people suggest he only came to the throne after the first revolt in AD 47, though this as with many things is by no means certain.

4.13 Coinage in the other Civitates

The nature of the transition in the territory of the client kingdom of the Iceni need not have been repeated elsewhere. Each LPRIA grouping could have responded in its own way depending upon its level of development before the conquest and the nature of its relationship with the conquering forces. A not dissimilar system to that of the Icenian coinage comes from Haselgrove's Southern coin series. Both comprised gold and silver fractions, though the Southern circulation area was not perhaps as closed to other Iron Age series as East Anglia appeared to be. It is interesting to note that the second client kingdom, that of Cogidubnus, probably covered much of the circulation area of this Southern Series. However, it must be admitted that opinions vary as to precisely where Cogidubnus's kingdom was. Chichester, Winchester, Silchester and Bath may all have been within it according to various authors (cf. Millett 1990, 68; Cunliffe 1988; 160, Salway 1984, Map III). Some have even suggested that it was far more extensive, comprising much of the South East including areas north of the Thames (Haselgrove 1984). Indeed the term client kingdom itself covers a wide variety of situations (Braund 1984) and we might be better advised to talk of the Iceni and Cogidubnus's territory as *foederati* - 'self governing' allies within the boundaries of the settled civilian provinces of the empire.

In our analysis of Icenian coinage, we saw that there was an interaction between both Roman and LPRIA currency systems, and the Roman one gradually took over. So can the kingdom of Cogidubnus be similarly found by plotting the location of mixed hoards?

> "At least twenty hoards and temple deposits contain both Iron Age and Roman coins. These mixed finds cluster in the known client kingdoms in Central southern England and East Anglia and have a complimentary distribution to the hoards with only Roman coins (up to Nero) which are concentrated in south-east England (Kent 1973)."
>
> (Haselgrove 1987, 204)

Rather than simply examining Roman and mixed hoards, our Icenian analysis should make us aware that many LPRIA hoards may in fact have been deposited in the Roman period. For example, the Honingham hoard contained no Roman coins in it, yet was structurally later than several other Icenian hoards which did contained some.

A corpus of LPRIA hoards has been compiled from Haselgrove (1987) and Van Arsdell (1989) (Appendix 4.11). The coins in each hoard have been converted from Mack and Van Arsdell's classifications to Haselgrove's periodization. In each case the latest coin period represented has been assessed. Whilst no Roman coins appear in hoards terminating with issues of period 7, some concluding in period 8 do contain Roman coin. Therefore *it is quite possible* that any of the hoards concluding in periods 8 and 9 are in fact post conquest deposits. The three types of hoard are therefore:

1. LPRIA coin hoards terminating in Periods 8 & 9
2. Roman coin hoards terminating before c. 75
3. Mixed coin hoards

These have been plotted in fig. 41.04. Icenian territory shows up very clearly as an open mixed circulation area, accepting both the pre-existing local LPRIA and Roman coinage. Indeed sites such as Woodcock Hall have produced extraneous British coins as well in post-conquest contexts, though here specifically with a military context. The other mixed hoards outside East Anglia are more dispersed. Apart from the hoard from Tunstall (an Eastern series hoard of two gold coins and an *aureus* of Claudius), all the hoards are potentially within the kingdom of Cogidubnus; but only on a maximum view of his territory. Otherwise no purely Roman hoards are recorded in the database before the Flavian period. The situation is therefore similar to that of the Iceni. The LPRIA coins probably continued in use for a while, with Roman coins only occasionally being hoarded alongside them, but never totally on their own. This interpretation is supported by the analysis of site finds by Haselgrove:

> "The most striking aspect of post-conquest deposition is, however, the separation between Roman civilian and British usage, and between the conquered territory and the client kingdom established in central southern England. ... Thus we may point to the contrast between the colonia and the extra-mural suburbs at Colchester, or between Insula XIV and the ribbon developments at St. Albans. London had no local bronze coinage, but the number of probable post-Conquest losses within the other two public towns north of the Thames is significantly smaller than at those within the client kingdom, Chichester, Silchester and possibly Winchester. ... But interestingly, despite British usage continuing in the client kingdom, it never apparently penetrated the class of newly emergent smaller nucleated settlements, eg. Neatham or Wickham Bushes. Coin use was Roman from the start - in marked contrast to similar sites north of the Thames.
>
> By inference then, British coin usage in the client kingdom continued largely as previously until Romanisation rendered it irrelevant."
>
> (Haselgrove 1987, 208)

Open circles - Iron Age coins only
Solid circles - Iron Age and Roman coins
Hatched circles - Roman coins only

Fig. 41.04 The location of LPRIA, Roman and Mixed hoards.

If we go outside the suspected areas of the client kingdoms, then mixed hoards disappear, and a parallel system appears to exist. There are LPRIA hoards, some of which may date to the post-conquest period and there are Roman coin hoards, but the two do not mix. Such was the situation identified from site finds by Reece (1979) in the territory of the Dobunni (Western series), where little overlap was found between the coin use at the contemporaneous sites of Cirencester and Bagendon. Cirencester produced mainly Roman coin, while Bagendon produced LPRIA coin. These territories may perhaps be characterised as running parallel rather than simply open systems in this period.

One final cluster of mixed hoards exist, off the map in fig. 41.04. These are a couple of Corieltauvian and Roman mixed coin hoards from Yorkshire (Lightcliffe and Honley). Haselgrove has suggested that these may indicate the post conquest use of British coin in the payment of auxiliaries raised in the province. This could similarly be used to explain the non-local coin in the fort at Saham Toney. However, the data for this is too small to be anything but merely suggestive (Haselgrove 1984, 41).

This regional division outlined above should not be over-emphasised. It would only require a couple more hoards in the right place to produce a totally different interpretation of fig 41.04. What would be useful would be a second method unreliant on hoards to see how post-conquest coin use related to the pre-conquest situation.

The Augustan monetary system offered a full range of denominations in gold, silver, brass and copper. Admittedly the supply of the *aes* coinage was problematic in the Claudian and early Neronian period, however copying certainly ensured there were small denominations around. The people of the Eastern and South Eastern currency areas may have adapted to this quite rapidly. In the LPRIA they also had a full range of denominations. However, in the peripheral circulation areas precious metal coinage dominated. Is this pattern reflected in the pattern of Roman loss?

In order to investigate this, the site lists were divided up into three zones depending upon their LPRIA currency systems:

Zone 1:	Full denominational LPRIA systems
Zone 2:	Precious metal currency systems (the South Western series has been included here)
Zone 3:	No LPRIA coinage

Table 4.13: The proportion of 'silver' coins in site assemblages, divided by LPRIA coin using zones. NOTE: This data excludes all military sites, and small towns with military associations.

	Zone 1 AV-AR-AE		Zone 2 AV-AR		Zone 3 None		Percentage silver		
	AE	AR	AE	AR	AE	AR	Zone 1	Zone 2	Zone 3
A Republican	1	17	0	6	0	11	94.44	100.00	100.00
B Mark Antony	0	0	0	1	0	8	-	100.00	100.00
C Julio-Claudian 1	27	3	11	8	16	4	10.00	42.11	20.00
D Julio-Claudian 2	148	3	61	4	138	2	1.99	6.15	1.43
E Civil War	1	1	0	1	0	0	50.00	100.00	-
F Flavian 1	80	8	41	16	60	9	9.09	28.07	13.04
G Flavian 2	57	7	36	6	27	7	10.94	14.29	20.59
H Trajanic	65	13	30	13	43	12	16.67	30.23	21.82
I Hadrianic	90	17	54	8	44	12	15.89	12.90	21.43
J Antonine 1	139	11	109	9	74	12	7.33	7.63	13.95

Zone 2 has the highest proportion of Roman silver finds from the Republican issues to the Flavian period. This shows the LPRIA preference here for precious metal coin continuing through into the use of Roman coin in the early period. The proportion remains higher than Zone 1 through until the Hadrianic period after which time no systematic difference remains. Again this feature was noted by Haselgrove:

> "The absence of post-conquest bronze coinages in the silver-using areas is to be viewed against the previous failure to adopt bronze and compares to Gaul. There, the polities striking extensive bronze coinages after the Conquest are apparently mainly those already producing base metal issues before 50BC - although difficulties in attribution and chronology preclude certainty."
>
> (Haselgrove 1987, 205)

There is a preference of LPRIA bronze using areas for Roman 'bronze', and LPRIA silver using areas for Roman silver. While a civitas by civitas study would be ideal, the database does not yet have sufficient in depth coverage to do this. The inference from this is that the functioning of Roman coin on non-military sites is related to the pre-existing LPRIA pattern of coin use.

4.14 Early Roman Silver

The *denarius* supply model outlined in section 3.5, indicated that there might have been a peak in the number of *denarii* in circulation in Britain in the immediate post-conquest period, however, the model also suggested that this had disappeared by 60, if not by 55. Two particular pieces of evidence were used to support the model. First the copying of Tiberian and Claudian *denarii* , a phenomenon which frequently relates to periods of shortage of coin (section 3.56). Secondly it was shown that while hoards were generally large in the first decade of conquest, when the total number suggested in circulation fell, hoards became smaller. Similarly when the model predicted a rise in the early second century, this too is reflected by a growth in hoard size (section 3.55).

The model can either be accepted or rejected, however, first a number of points need to be made to put the peak into context. First the replacement of British silver in circulation by Roman silver. Secondly the money on loan to the Iron Age elite in the immediate post-conquest period and other contributory factors which lead to the Boudican revolt.

Whatever the role of Iron Age coinage in post-conquest Britain, it is unlikely that all of it ended up in either post-conquest hoards or votive deposits. Much of it must surely have been exchanged for Roman *denarii* . The process by which this was done we do not know and probably cannot know. However, the alternative that the silver in circulation in Britain all went to ground is not particularly likely. Given this, a sharp rise in the number of *denarii* in circulation in Britain is entirely to be expected. This rise would be on top of the quantity of money being carried by the army of conquest itself. The old Iron Age coin would presumably have eventually found its way into the imperial melting pot.

This factor accounts for an initial rise, though one that would level out once much of the Iron Age coinage in circulation had been replaced. However, Iron Age coin is not uncommonly found in Flavian contexts, does this mean that the peak is too early? Of the mixed hoards with known *termini post quem* (Appendix 4.10), eight of the 13 close with Claudian or earlier coins, two end in Nero's reign (both from the Icenian territory) while only three have post Neronian closures. This suggests that less British coin was around from the Neronian period onwards. If the rise in the number of *denarii* in circulation was due to their replacement of Iron Age silver, this evidence would suggest the rise would not be sustained much into or beyond Nero's reign, as indeed the model indicates. However, none of this explains the dramatic fall in the number of *denarii* in circulation suggested.

~~in the later period. Whatever, this only explains an initial rise and cannot account for the dramatic fall immediately afterwards~~. ?

A second possible cause for the Claudian peak is the early but short term presence of money on loan to the elite. The most notable example being Seneca who we are told by Dio (LXII, ii, 1) had 10,000,000 HS on loan in Britain and recalled it all shortly before the Boudican revolt. This may be added to by payments from Claudius to prominent Britons which were also demanded back by the procurator, Decianus Catus. Dio places much of the blame for the revolt upon his shoulders. Quite how these loans should manifest themselves in the archaeological record it is unclear. Would the loans have actually appeared as physical coin in the province? If the coin had been used to pay for Gaulish stone-masons to construct romanized buildings (cf. Blagg 1984, then much of

this money may have only been transiently visible in Britain. However, much of this construction work post-dates this early period. Since few complicated financial instruments existed in the Roman world beyond maritime legislation, I believe that the early loans would have been in the form of coin. Their recalling in the immediate pre-Boudican period (together with healthy interest payments) had a dramatic effect if the *denarius* supply curve is anything to go by. Whilst Tacitus' account of the causes of the revolt must generally be preferred because of his source and proximity in time, it is unlikely that Dio's rather different emphasis on the repayment of the loans is completely without foundation.

I believe that the early *denarius* peak suggested by the *denarius* -supply model is consistent with the other evidence we have.

The shape of the supply curve, however, flatly contradicts some established beliefs. Sutherland states that "Nero's reform of the coinage has as its immediate results the multiplication of silver current in Britain and the tendency of the older and heavier coins to disappear..." (Sutherland 1937, 14). That the number of *denarii* of Nero outnumber those of Claudius in Britain is not contested, but Sutherland's conclusion still does not necessarily follow. The quantity of Republican *denarii* in Britain outnumbers both Claudian and Neronian issues, but that does not mean to say there must have been more *denarii* in circulation in Republican Britain than in Claudian or Neronian Britain. Such an argument would be based upon the static view of monetary circulation (cf. fig. 31.01). There is no reason why all Neronian *denarii* should have entered Britain during his reign. Many may have arrived in subsequent periods, possibly from the mint, possibly from inter-provincial exchange.

4.15 Early Roman Bronze: Claudian copies

Claudian copies form the core of a forthcoming analysis by Robert Kenyon. This section has no intention of attempting to pre-empt this. Rather, it sets out to draw a specific link between the manufacture of Claudian copies, their chronology and their relationship to other metallurgical changes taking place in Britain at the time of their issue.

The copying of Claudian *aes* coinage is a phenomenon not of Britain alone, but of the Rhineland, Gaul and Spain. The first copies to arrive in Britain were probably minted on the continent arriving with the legions in 43. Shortly thereafter British production probably began. The supply problem was only sorted out by the re-opening of the mint at Lugdunum by Nero in 64. In the Rhineland, Gaul and Spain this copying is not particularly remarkable. The local manufacture of coin to fulfil a shortage of low value coinage happened time and again in the Roman west. However, in Britain the original

coins are in a decided minority, and the use of Roman bronze coin was hardly an established practise. Why therefore were these coins copied rather that the pre-existing LPRIA bronze? The usual answer is to see the earliest minting as a function of the army's needs, followed only later by more wide spread production:

> "It seems possible that, originally, copies were made semi-officially to supplement existing supplies of cash for the legions, being fairly accurate in weight and style (grade 1). On being absorbed into the currency system of the province, these would themselves be liable to imitation, perhaps at the larger tribal centres... but with a falling off in both skill and weight (grade II)."
>
> (Sutherland 1937, 13)

There is not universal agreement however. Boon particularly dislikes the idea of regional 'quasi-official' production by the military. First he pointed out that army pay was collected in coin from the procurator's office (eventually to be found situated in London) on the basis of an estimates of expenditure presented to it (Boon 1988, 117). On the basis of this there would be no mechanism or need for coin to be manufactured locally by the army. It was contrary to the system:

> "...the chief reason why the theory of army-manufacture of coin must be dismissed is that the fact that the army units drew their pay against an estimate of the amount, and under an obligation to account later, from the procurator's office. In any case, the 'quasi-official' explanation is absurd: if some copies were counterfeit and others made by authority, some tolerated and some rejected as false, the result would be chaotic. It is proper to regard them as one and all false..."
>
> (Boon, 1988, 123)

The justification for coin coming directly from the procurator comes from a very fragmentary wooden writing tablet found in an early well from the legionary fortress of Caerleon (Tomlin 1986). It appears to be a series of future troop movements, including a body of men going to present the estimate of expenditure to obtain the *stipendium* . However, in the first instance the document does not specify that headquarters meant the procurator's office. Secondly I would have imagined that much of the coin was collected in *denarii* rather than base metal (though this is perhaps more of a problem of my imagination), and thirdly the document comes from a context dating to 75-85 and presumably post dates the period of Claudian copying in any case, indeed the site at Caerleon was only founded in the Flavian period, so the document is unlikely to be residual.

Empirical observations can be made associating the loss of Claudian copies specifically with military sites. Woodcock Hall is a good example (Brown 1986). Here there was an LPRIA site overlooked by a Roman fort on the other side of a stream. Systematic meta-detecting revealed large numbers of Iron Age coin focused upon the LPRIA settlement. Official Roman coin was found on both sites, however Claudian copies

concentrated primarily in the fort. As Brown says: "the concentration of *aes* copies within the confined area south of the stream suggests some restraint whereby circulation of these coins was confined effectively to military personnel." (Brown 1986, 10). Other associations such as the large numbers from Usk and Hod Hill mean that a military function or need for the coin is very likely. Even if the coin gradually spread out to become used by the general population later on, a military link cannot be dismissed. But first before we make all kinds of conclusions, let us examine some other kinds of evidence.

In order to copy coinage one thing that is needed is metal. The position of brass in the discussion of Claudian copies has been rather neglected, however it can throw some interesting light upon the chronology of the copies themselves and other transformations in the metallurgy of other artifacts in circulation in Britain.

In many ways brass can be considered as a prestige metal in LPRIA Britain. Whereas gold and silver could be mined in Britain, brass had to be imported; the technological knowledge to make it in this country was not established (the only possible evidence comes from some signs of brass working at Baldock). Its circulation appears to have been restricted to the form of brooches (Bayley 1989). This restriction in itself suggests some kind of special value placed upon the metal. At the time of conquest, therefore, brass could be supplied in only three forms: LPRIA brooches, genuine Roman *sestertii* and *dupondii*, and other imported metalwork. It is within this context that we must analyse the production of Claudian copies.

Whilst *asses* were originally made from copper, *dupondii* and *sestertii* were made from brass, and this is indeed what they appear to have been copied in (Bayley 1987). Evidence may be summoned which suggests that brass was deliberately imported in the mid first century, probably to make the copies. This takes the form of three brass ingots. One from Sheepen, Colchester measuring 91 x 15 x 0.5 came from an AD 43-60/1 context. Paul Craddock's analysis demonstrated it to be a very high zinc brass (Musty 1975). The second comes from another early context with military associations, Kingsholme (Gloucester) (Justine Bayley pers com.). A third is known, this time outside a well dated context from Claydon Pyke. This however can be paralleled with similar bun-ingots known from a 1st century wreck off Corsica. The first two are good early sites, and the third, while not specifically of the early conquest period is still indicative of the long distance supply of brass, since the metal is too pure to have been produced by melting down any of the LPRIA artifacts which were in Britain (the brooches tended to contain some tin which is absent from the ingots). However, there is reason to believe that the deliberate importation of brass, if there was such, in the early period of copying did not last, nor was it sufficient.

A systematic bias towards the copying of *asses* rather than brass coin can be found. The first thing to point out is that the proportion of *asses* copied was higher than the proportion of official *asses* in general circulation (Table 4.10). Either this was because of a preference for smaller valued coinage or because brass was in relatively short supply. However, we can move beyond this to add a chronological dimension to the picture. Throughout the 40s, 50s and early 60s there was a shift in production away from minting both brass and copper coins to concentrating upon copper asses. This can be seen from the coins at both Usk and Colchester.

Table 4.14: The ratio of Claudian denominations copied compared with the proportion in circulation. Colchester data from Kenyon (1987)

		Pre Neronian Aes from the Site Find database		Colchester 1971-82
Denomination	Metal	Real (n=153)	Copies (n=484)	Copies (n=124)
Sestertius	Brass	12.4 %	1.4 %	0.8 %
Dupondius	Brass	17.0 %	9.9 %	23.4 %
Dupondius/As	Brass/Copper	3.9 %	1.4 %	0.0 %
As	Copper	65.4 %	87.2 %	75.8 %
Quadrans	Copper	1.3 %	0.0 %	0.0 %
TOTAL		100.0 %	100.0 %	100.0 %

Using the coins from Usk and the broad rule of thumb that the better copies were earlier, and the degenerate copies later in date; one can see a shift in production from *dupondii* to *asses* throughout the period (Table 4.10).

Table 4.15: Claudian Copies at Usk (after Boon 1988)

Denomination	Metal	Grades I & I-II	Grades II & II-III	Grades III & IV
Dupondii	Brass	33.3 %	10.0 %	8.7 %
Asses	Copper	66.7 %	90.0 %	91.3 %
Sample		n = 18	n = 30	n = 82

The picture from Colchester is similar (Kenyon 1987). The grading of the copies here was slightly different, replacing the earlier scheme of Grades I to IV with three grades A-C. Again one can examine the proportion of denominations copied in each grade (Fig. 41.05) and again it would appear that brass coins became increasingly out of favour as articles to forge. Does this imply increasing pressure upon the source metal? If this hypothesis is correct then chronological changes in the quality of the brass alloy used might be expected, with copies starting off with relatively good brass and concluding with more variable alloys. So let us now turn to re-work Bayley's analysis of the *dupondius* copies from Colchester.

In Bayley's analysis the copies were ordered by archaeologically phased contexts (1987). Looked at in this way no systematic pattern in the composition of the coins was found. This was due to the residuality mixing up the order in which the coins might actually have been minted. However, Kenyon in his preceding article provided a alternative way to order the coins. By examination of the weight and size of numerous

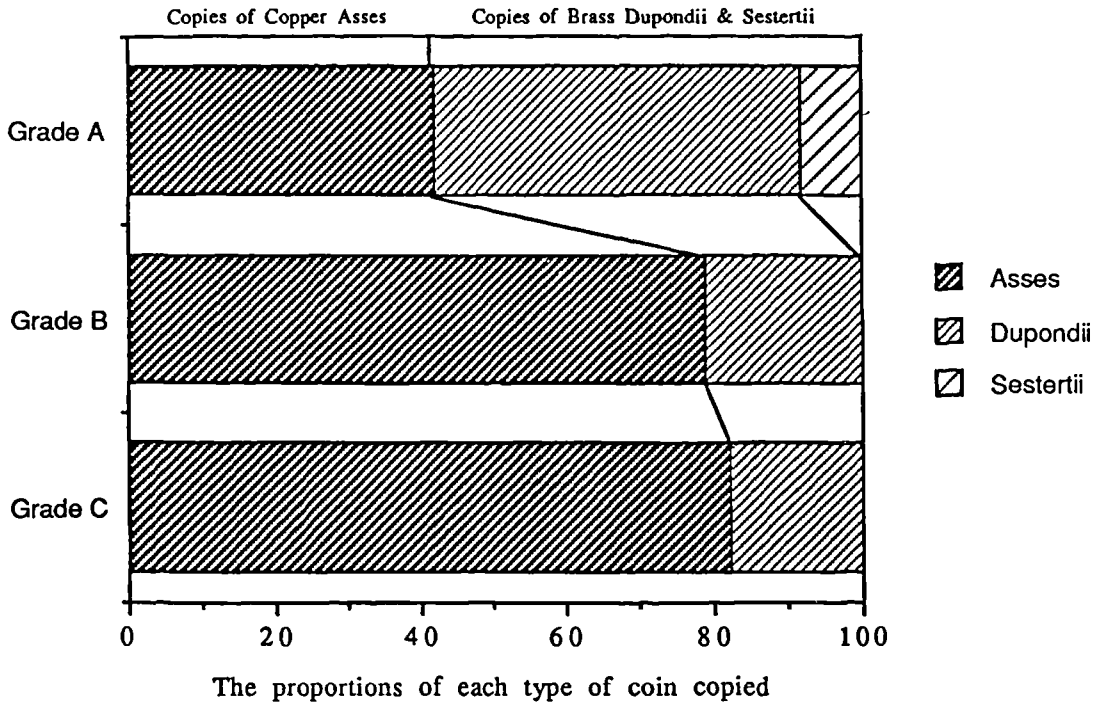

Fig. 41.05 Claudian copies from Colchester: grades & denominations.

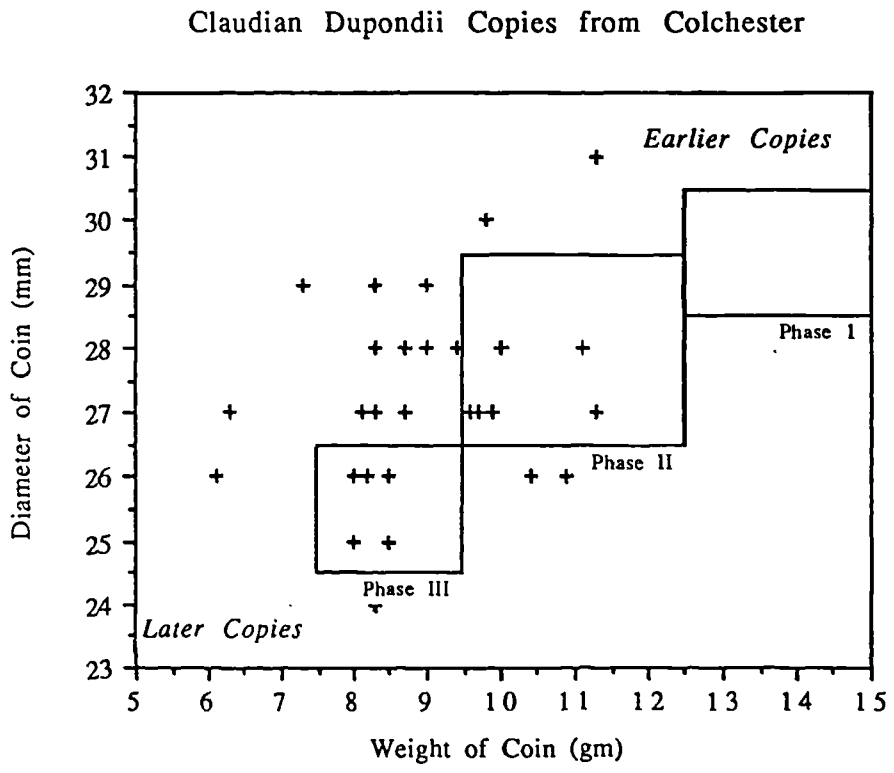

Fig. 41.06 Claudian copies from Colchester: weights and sizes.

copies from a wide variety of sites, Kenyon proposed three main phases of 'Claudian Copy' production, though the precise justification for this awaits publication.

Phase I Here the copies were very close in date to that of their originals. None of these were found in the group of coins from Colchester under examination, and therefore none were included in Bayley's analysis.

Phase II 44-c.49

Phase III c.49-60/1. (Kenyon 1987, 39).

The three standards he proposes are marked in fig. 41.06. Many of the Colchester coins were worn, and so were lighter than the original standard they would have been minted to. Nonetheless, we can approximately arrange these coins in order of date by working out their position along a transect from the top-right-hand corner of the graph (heaviest and biggest) to the lower-left corner (lightest and smallest) (Table 4.10).

Table 4.16: XRF Analysis of Claudian copies.
The data derived from Bayley (1987) and Kenyon (1987)

No.	Small Find Number	Diam. (mm)	Weight (gm)	Wear (1-9)	XRF Ratios Zinc	Lead	Tin	
1	BKC 189	31	11.3	3	70	-	-	Earlier Copies

28	BKC 5224	24	8.3	4	63	-	-	
29	BKC 4707	26	6.1	9	25	5	-	Later Copies

Note:
Zinc ratio is about 100 for a brass containing about 20% zinc.
Lead ratio is about 20 for alloys with around 10% lead.
Tin ratio is about 6-7 for alloys with 5-7% tin. Also very low levels of tin cannot be detected using this technique, owing to a secondary copper peak.

It is occasionally suggested that the reason why copies tend to be lighter than their original prototypes is that they are made from melting down the genuine coin and

reminting them at a lighter weight; herein lies the profit. So could British copies have been made from melting down genuine *dupondii* and *sestertii* ? In this case the model does not work. First it would not explain why the earliest copies were the same size and weight as orthodox issues, there would have been little profit here. Secondly, the extreme variability in the composition of the copies does not suggest that their sole metal source was the genuine article. Two trends can be seen in the results. The first is that in the earliest coins there is very little lead in the alloy, suggesting a fairly pure source for the minting of these coins. The second point is that the only coins to register the presence of tin are very late copies; however the fact that this method cannot detect levels below 1-2% must be remembered. I think these are real trends, but further quantitative analyses including more of the earlier better copies would be required to confirm it (cf fig 41.06).

How do these compositions compare with the brass ingots mentioned above? The ingots contained no sign of tin at all, and only the Claydon Pyke example contained a trace of lead. Otherwise they were generally of a much higher zinc content than these coins (around 20-27%). If these ingots were being imported for the production of brass copies, they were certainly being diluted by extraneous supplies, particularly in the later period.

The other artifacts in Britain which contained brass, as mentioned, were LPRIA brooches. These underwent a radical transformation in their alloy composition at just this date. Whilst nearly all brooches were made from brass in the LPRIA, upon the conquest this picture rapidly changed with a shift to leaded bronze (fig. 41.07). This can in no way be seen as a technological advance. Leaded bronze made far worse springs, and forced a change in brooch design to the use of a hinge replacing the spring. Brass also had a far more golden appearance, which leaded bronze did not possess. It was possibly to counteract this loss that many post conquest brooches had a silvery finish added to them by tinning. If technologically the new leaded bronze was not as good, and visually it was not as impressive, why did the change take place? Perhaps the leaded bronze was cheaper enabling more brooches to be produced? If so this did not result in any larger numbers of brooches being produced in the early Roman period (Creighton 1990, 188). The simplest explanation is that brass was for some reason in short supply and alternative alloys had to be found.

We have established that whilst brass coins were copied, the numbers copied declined with time. Two reasons could account for this:

1. A desire for low value *asses* in preference to *sestertii* and *dupondii* .
2. A shortage of brass to manufacture such coins.

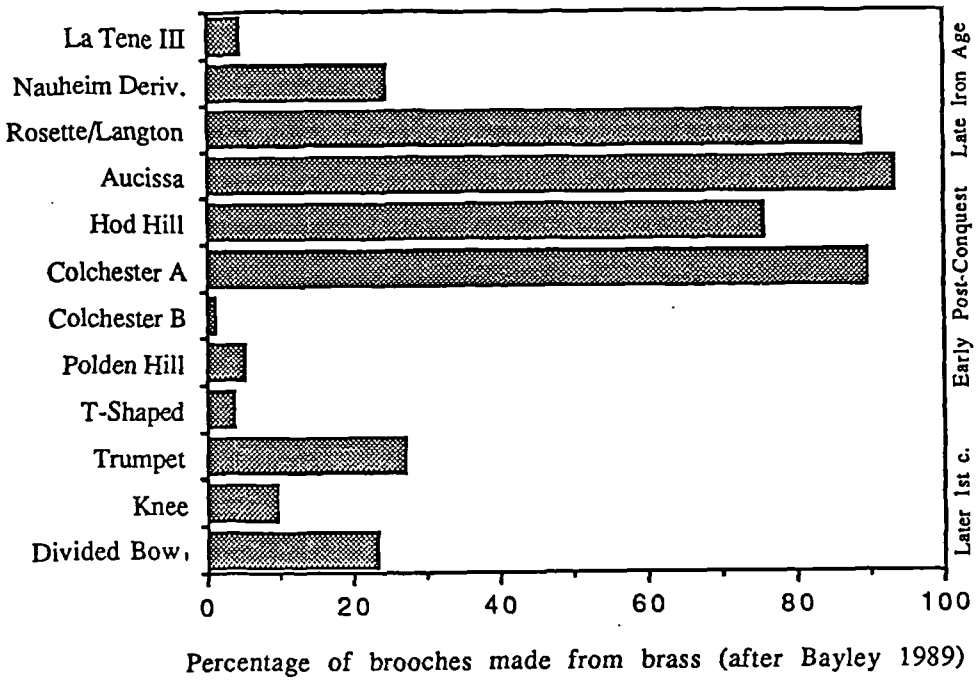

Fig. 41.07 The proportion of LPRIA and Roman brooches made from brass.

The change in the metallurgy of brooches strongly suggests that there was a shortage of brass in this period. Indeed it might be possible to go further and suggest that brooches were being melted down to be converted into coin, though to argue this on the basis of the analyses done so far would be premature. The conversion of brooches into coin may at first seem rather tenuous. However, if we look a bit further into how brooches and coinage functioned within Late Iron Age society the differences soon start to blur. Brass, like gold and silver can, because of its scarcity, effectively be treated as a precious metal.

In their range of depositional contexts, late Iron Age brooches have parallels with Iron Age coinage. Both coins and brooches are frequently found at Celtic and Romano-Celtic shrines, Hayling Island and Harlow being examples. Indeed at Harlow almost a hundred brooches were found. The Celtic coins occurred in two major concentrations within the temple precinct, with a thin scatter lying elsewhere. The brooches however had a different distribution, just under half came from within the central building itself, while as with the coinage there was a broad scatter in the precinct (France & Gobel 1985). A second example comes from Woodcock Hall (Brown 1986). Two particular concentrations of Iron Age coin were found by the brook (1986, 9, fig 4). The early forms of bow-brooches concentrated in precisely the same area (1986, 13, Fig 6). This suggests either a couple of widely scattered hoards (in which brooches and Iron Age coins were hoarded together) or two votive deposits. In either case, the depositional relationship (and therefore functional relationship?) between the coin and brooch is established. A final example comes from South Ferriby (South Humberside). Here, at the turn of the century when much of the site was being eroded into the Humber, a large quantity of metalwork (Iron Age coins, Roman coins, brooches and some other copper alloy artefacts) were discovered, largely in the vicinity of a natural spring called Cadwell (St. Chad's Well) (Sheppard 1907a). Not only this, but a hoard of c.25 Iron Age coins was discovered around 1904, containing with it three Romano-British brooches; two Colchester types and a trumpet brooch (Sheppard 1907a, 1907b; Allen 1963). These have frequently been dismissed because of their uncomfortably late date; however there is no *prima facie* reason to do this.

One frequent feature which can be taken to emphasis the votive nature of brooch deposition is the deliberate cutting of the brooches, similar to the twisting of swords and other equipment upon deposition. Brown noted this with the brooches from Woodcock Hall. They were frequently cut in two. The possibility that this was a preliminary stage to placing them in a crucible prior to melting them down was considered, but rejected. The reason was that whilst some of the larger brooches were severed, many of the smaller brooches were likewise cut, even though complete they were still much smaller

than some of the larger halves. I have also noted the same phenomenon on four sites in South Humberside including South Ferriby.

This discourse has simply been to establish that in the religious and hoarding sphere of Late Iron Age and Early Roman life, brooches and coins *could* fulfil similar functions. The circulation of coinage could be used to reinforce social status while brooches could be used to display social status.

So we come back to the effect of the conquest. If the Late Iron Age coinage was all eventually called in, whether by taxation, tribute, booty or any other mechanism, it was replaced in circulation by *denarii* . In this kind of context, I see nothing particularly strange about other prestige-goods being converted into the brass coinage. Of course it may be totally coincidental that brooches ceased to be made of brass at more or less the same date that the copying of *dupondii* required brass, but it seems unlikely. What we appear to have is a narrowing down of the variety and types of primitive currencies in circulation in Late Iron Age Britain to a unified monetary system. Mobile wealth is being converted into something more useful to the elite in integrating itself with the rest of the Empire.

If we wished to suggest a model for the supply of brass in this period to make the copies, then I would suggest the following:

Phase 1: Claudian *dupondii* copies are initially made from good brass. This was probably officially supplied. The slight evidence for this supply could come in the shape of three brass ingots: however such imported brass, as all three probably were, was not enough. Though the earliest brass copies started out un-leaded and still had a good proportion of zinc, this situation did not last.

Phase 2: Official supply of imported brass may have ceased or simply not gone far enough, so other resources within Britain may have been looked for. The presence of lead certainly suggests that the brass was being further alloyed with the addition of other metals, to make the brass go just that little bit further. Right at the end of the sequence we start to see tin showing in the alloy, which until now this has failed to register. Bayley's analysis of the brass brooches (1989) clearly shows that most of the common late Iron Age types contained some tin in their alloys so this might indicate a conversion of one to the other.

Whatever, this idea suggests that a co-ordinated analysis of different types of metal work in LPRIA and post-conquest Britain might enable us to make some more secure statements about the inter-relationship between local copying and the metal reservoir in

Britain. Similarly such an approach might be appropriate to other periods of copying as well in the Roman period.

4.16 Conclusion

The dominant view of the Iron Age to Roman monetary transition in Britain has been that of Reece followed by Haselgrove:

> "The monetary impact of the invasion has recently been assessed from the Roman side by Reece (1979), whose conclusion, and one with which I would certainly concur, is that generally the indigenous coinage was rapidly replaced by the imperial coinage, largely because confronted with Roman usage it was essentially irrelevant, and not because it was officially suppressed."
>
> (Haselgrove 1984, 41)

The effect of Reece's paper has perhaps polarized the difference between the systems more than is warranted. Various types of continuity did exist between the Iron Age and Roman monetary use.

1. Roman and British coins were hoarded together is some regions, though admittedly not everywhere. In the case of the Iceni we see a gradual transition from hoards dominated by British issues to totally mixed hoards.

2. Areas with silver rich LPRIA coinage systems show a preference for Roman silver coin, and areas with LPRIA 'bronze' currencies show a preference for Roman 'bronze' coinage up until the late Flavian period.

3. Brass in LPRIA Britain was restricted to brooches, items which could variously be used for status display or votive offering. In the early Roman period the use of brass was restricted to military fittings and the local manufacture of Claudian *dupondius* and *sestertius* copies. The contemporary change in the metallurgy of brooches from brass to a leaded bronze suggests a continuity in the status of the metal from the one period to the other.

Reece's point was primarily based on the difference between the site assemblages from Bagendon and Cirencester. This is an observation which I would certainly not wish to question. However, given the points above it is difficult to argue that the use and function of Roman coin in post-conquest Britain was something totally different to the functioning of the LPRIA issues. If the function of each currency was totally distinct then we would not have expected the pattern of deposition of coin in LPRIA contexts to have had a determinate role in the early Roman situation. But it appears that it occasionally did. It is commonly believed that LPRIA usage was dominated by military, political and social use rather than commercial exchange. Different types of

coin had different purposes. The mistake is to assume that the Roman currency system, which appeared to be an integrated whole orientated towards commercial exchange, in fact operated that way. If the social structure of the LPRIA survived the conquest relatively intact, then the continuance of earlier patterns of circulation and exchange, even if using a new medium, should not be unexpected.

4.2 The circulation of bronze and silver

In this section the relationship between the bronze and silver circulation systems is discussed. First a thorough examination is made of Walker's Bath coin report to evaluate his estimates of the number of bronze coins in circulation in Britain (Section 4.21). Secondly an attempt is made to derive aes supply figures as done previously for denarii. This is achieved with sestertii, but alas not for asses and dupondii because of the quality of the data. Walker's results are looked at to see if they support the model, which broadly they do (Section 4.22). A second method for reconstructing Bronze supply figures is then described based on wastage rates. The results are found not to be dissimilar to those from the previous model (Section 4.23). The results of both of these studies are then assessed in the light of the denarius data and other information about the circulation of both silver and bronze coin (Section 4.24). Following this literary sources are used in addition to reassess the role of bronze in the circulation system (Section 4.25).

4.21 Walker's Bath coin report

The starting point of any discussion about the supply about *aes* coinage to Britain in AD 43-260 must be David Walker's report on the coins from the sacred spring at Bath (Walker 1988). The assemblage comprised 12,595 Roman coins together with some Iron Age and Post-Roman issues. Its importance lies in the analysis of the first to third century *aes* coins. Walker divided up the material into three main phases (table 4.21). During the first phase Britain was supplied sporadically, only receiving coin when the mint at Lugdunum was in operation. Some coin came over from Rome, but with the exception of Domitian's issues of AD 86-87, never in any quantity. From the reign of Nerva a regular supply arrived, however, from AD 197 this ceased and thereafter little new *aes* was seen in Britain. During the period of regular supply Walker managed to identify a series of extra-ordinary issues which appear to have been directed specifically towards Britain. From a die link analysis of those issues which circulated in Britain alone, he calculated estimates for the total quantity of *aes* in circulation in Britain in the Hadrianic and Antonine periods.

Since this work is liable to become the set word on the subject for a long time to come, it is worth conducting a detailed criticism of the analysis and an assessment of the reliability of the results. First the biases in the nature of the Bath deposit will be assessed. Secondly the effect of this on his division of supply into three periods will be examined. Thirdly the attribution of a 'British association' to the FORT RED issue will be questioned. Fourthly the establishment of Walker's *aes* supply figures for the Hadrianic and early Antonine periods will be assessed.

The biases in the Bath coin deposit

What are the biases in the Bath assemblage? Since the deposition of each coin was a conscious action one might suspect that denominational selection took place. Walker contrasted his list with the coins from Richborough and found that there were significantly fewer silver coins discarded as votive offerings at Bath. One silver coin to 24.86 *aes* at Bath compared to 1:5.77 at Richborough. So one bias in the deposit was clear. A similar analysis was conducted to detect differences in the deposition of *sestertii* and other smaller bronze coins. In this case no marked patterns emerged (Walker 1988, 284).

A second method analysing the differential deposition of denominations arose from the die link study. The series of *dupondii* and *asses* of Antoninus Pius which circulated principally in Britain were analysed. Estimates were created for the volume of each issue in circulation in Britain: 409,000 *dupondii* and 1,756,000 *asses* . Since the numbers of each actually represented at Bath were known (69 *dupondii* and 219 *asses*) it could be stated that the *dupondii* at Bath represented about 0.016% of the entire issue, while the *asses* represented 0.012%. This suggests that if anything there was a slight predilection for the deposition of *dupondii* rather than *asses* in the Antonine period (Walker 1988,303). However, the figures for the *aes* of Marcus Caesar showed the opposite pattern. The issues were estimated to be 360,000 *dupondii* and 280,000 *asses* , represented at Bath by 19 *dupondii* and 54 *asses* . This makes the proportion of the issue of *dupondii* deposited at Bath 0.0052%, and *asses* 0.019%. The sample size of the Marcus Caesar *dupondii* is admittedly low, but in general there appears to be no consistent pattern of selection.

In conclusion whilst a significant bias can be shown towards the deposition of bronze at Bath in preference to silver, no such differentiation can be seen within the *aes* denominations.

A second cause of bias in the sample is the assumption that the coins which were deposited were similar in proportion to those recovered. That is to say that there are no chronological biases, however, Walker admits there are problems with this:

> "...some coins would have been lost every time the sluice to the east of the spring was opened, while when the sluice ceased to be used the coins which were thrown in presumably remained undisturbed. This can only mean that our figures have a bias against the earlier periods in favour of the later periods, but how great this bias is, and how many of the earlier coins have been lost this way we have no way of knowing. All we can do is assume that the coins recovered reflect the proportions of the coins originally lost..."
>
> (Walker 1988, 283)

One way of testing to see how biased the Bath assemblage is would be to compare it against the *aes* from the site-find database. Both lists have been divided into *sestertii* and AE2, and then into the chronological divisions outlined in table 2.21. The differing proportions of coin are displayed in fig. 42.01. Both graphs show that Bath under-represents the quantity of early *aes* discarded on sites. With *séstertii* the cross-over point between under- and over-representation comes in the late Hadrianic/early Antonine period (Groups I/J). With the *asses* and *dupondii* the cross is earlier in the mid Flavian period, this is a factor of the dominant presence of Claudian copies (D) in the site-find database and their relative absence in the Bath deposit. This under-representation of the earlier issues must be recalled when we discuss Walker's division of the supply of Bronze into three periods. For the moment however these are the three principle biases affecting the Bath coin list:

1. There was a bias in favour of *aes* coins being deposited at Bath, in comparison with site list assemblages.

2. No significant biases can be found between the deposition of the different *aes* denominations.

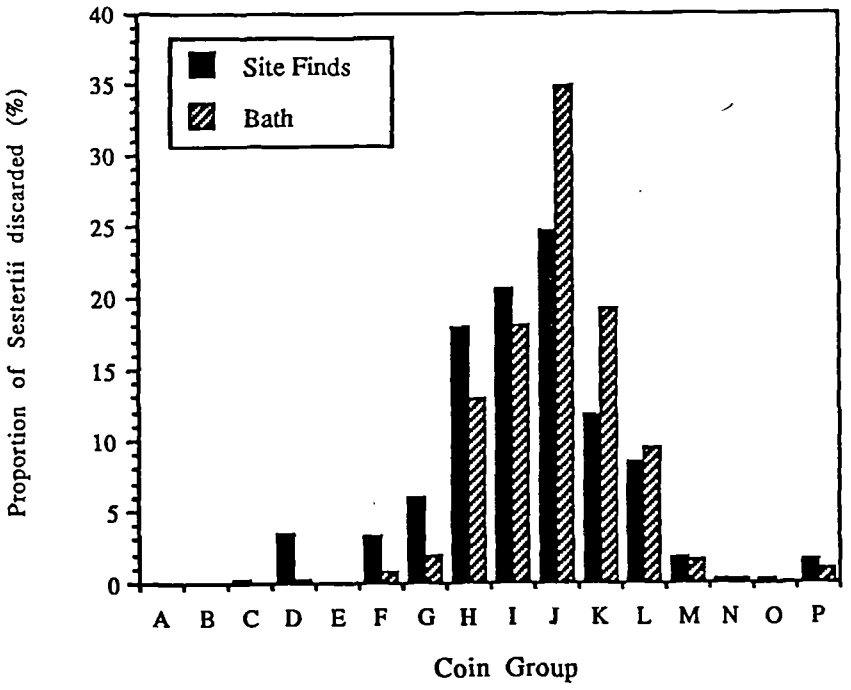
3. It can be demonstrated that the Bath list under-represents Julio-Claudian and early Flavian coinage. This may either be a function of the date the temple was established, or a pattern caused by the opening of the sluice washing out the spring.

The division of supply into three periods

Table 4.21: Supply of *aes* to Britain (After Walker 1988)

1. AD 43-96: Period of sporadic supply.		
The main injections of aes were as follows:		
	AD 64-7	Nero (Lugdunum)
	AD 71-73	Vespasian (Lugdunum)
	AD 77-78	Vespasian (Lugdunum),
	AD 86-87	Domitian (Rome)
2. AD 96-c.197: Period of regular supply.		
Issues particularly associated with Britain were:		
	AD 119	Hadrian - Britannia asses
	AD 122	Hadrian - FORT RED asses & the 'casting mint' issues
	AD 128	Hadrian - Salus and Sabina asses
	AD 153-55	Antoninus Pius - Britannia asses & other issues
		Clay (1989, 214) would add further issues to this list including sestertii of Antoninus Pius.
3. AD c.197-260: Period of minimal supply.		
	AD 198-222	Very minimal supply
	AD 222-260	minimal supply

It is possible to plot all of the Bath coins by issue date, divided up into the different denominations. This has been done in fig 42.02. The construction of these graphs is



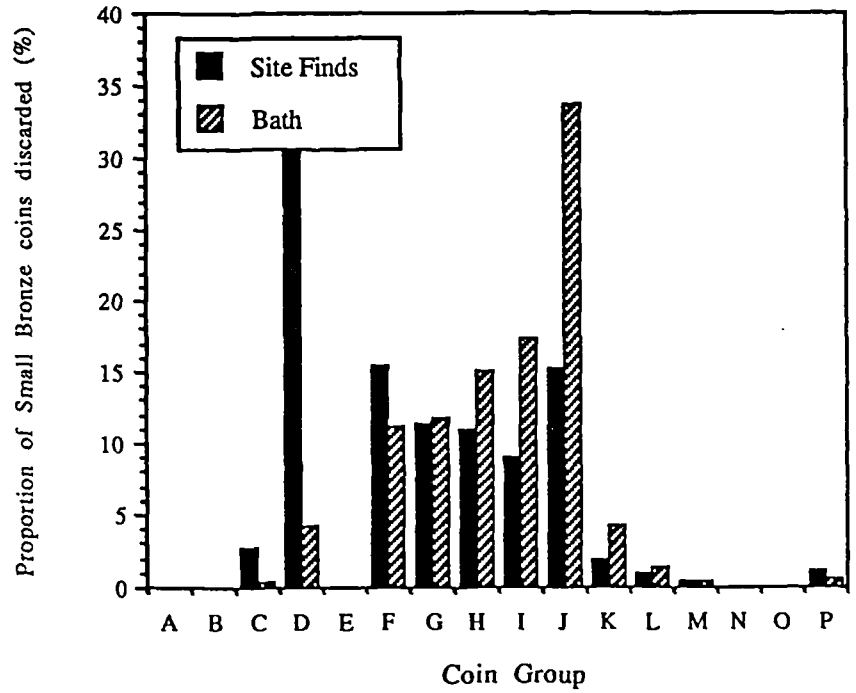


Fig 42.01 Biases in the assemblage from Bath: a) *sestertii* , b) *dupondii* and *asses*

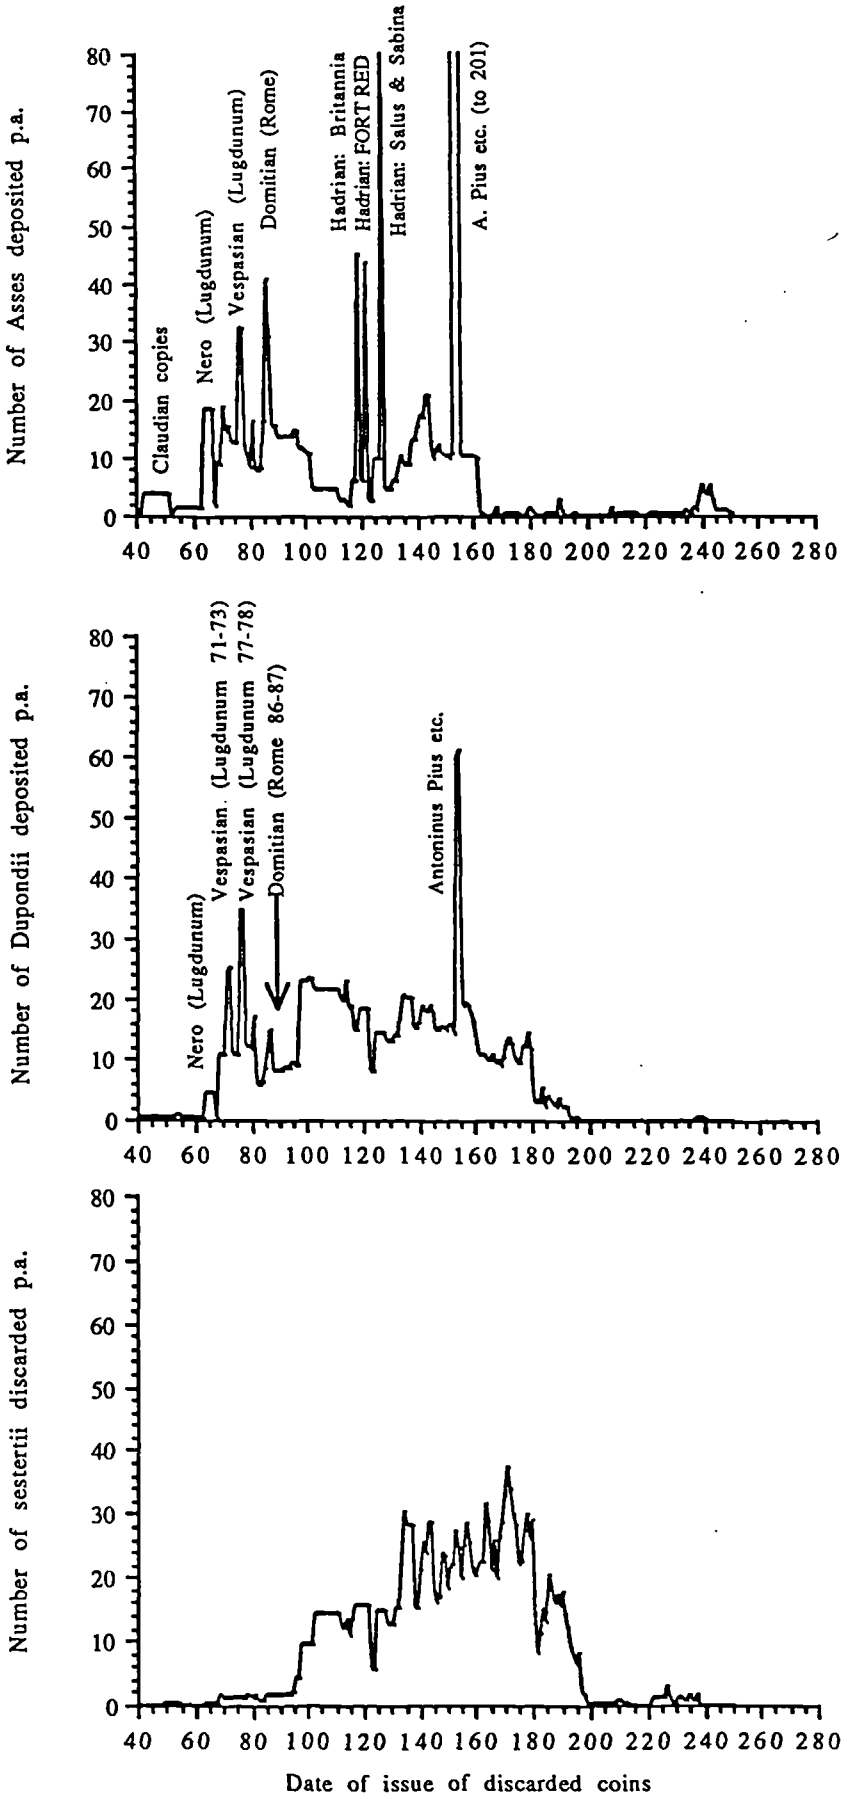

Fig 42.02 Bronze coins from Bath: deposition by denomination

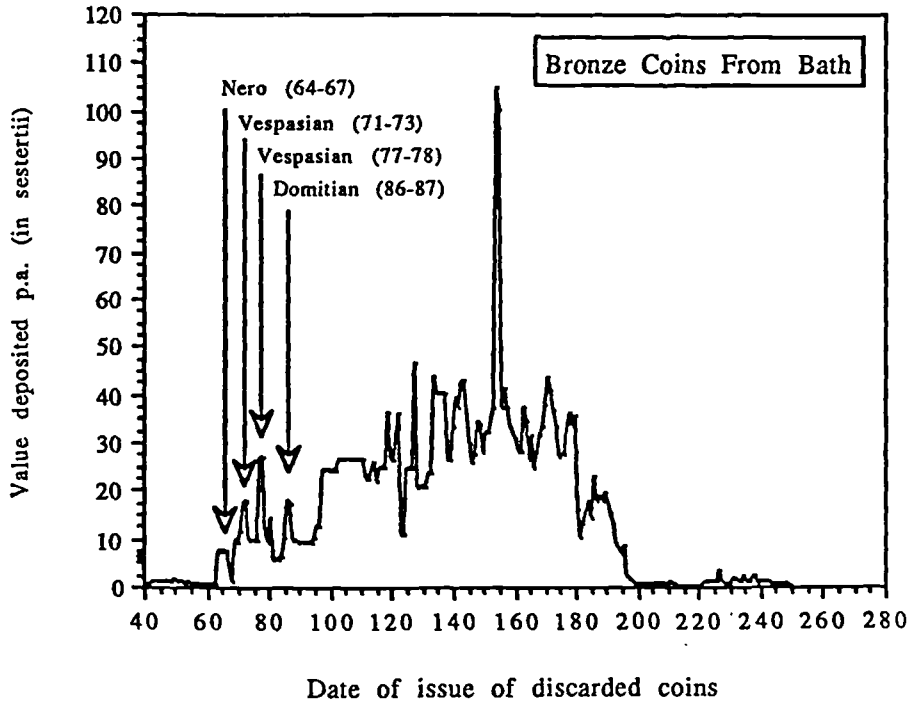

Fig 42.03 Bronze coins from Bath: value deposited pa.

straightforward. A *sestertius* of Antoninus Pius of AD 139 is plotted as one *sestertius* in that year; whereas one of AD 151-152 is plotted as half a *sestertius* of 151 and half of 152, and so on including all the coins except those simply ascribed to 'Illegible coins of the first-third centuries'. A composite graph calculating the value of the *aes* together (in *sestertii*) is given in fig. 42.03. The graphs show clearly the early dominance of the *as*, countered by the late predominance of *sestertii* . It is however instructive to note the almost total absence of Claudio-Neronian *sestertii* , whist these make up about 4% of the site-find database. This is part of the bias caused by the sluicing out of earlier finds mentioned above.

One factor blurs Walker's periodization of the supply in these illustrations. In the period of sporadic supply (AD43-96), the dating of some less well preserved issues to simply the emperor's reigns smooth out some of the peaks in the curve defined by many of the fully identified coins. Otherwise Walker's division corresponds quite well with the graphs. One point worth noting, however, is the gradual decline in supply during the later Antonine period, from c.170-197, before Walker's period of minimal supply.

In conclusion Walker's three period division is broadly correct, however:

- The Bath list may understate the early input of *aes* due to the under-representation of early coins in the Bath deposit.
- The period of 'regular supply' does not simply cease, but a progressive decline takes place the early Antonine period onwards.

The FORT RED issues and their circulation in Britain and the Continent

Next we examine the issues with British associations. Table 4.22 repeats some of Walker's data for these issues, alongside the corresponding data from the site-find database. With the coins of Hadrian, Sabina and Antoninus Pius there is a good correlation between the two. However, in the case of the small bronze of Faustina I (RIC 1162), Faustina II (RIC1395) and Marcus Caesar (RIC 1322), the comparisons are not as close. In the case of Faustina I, the proportion of RIC1162 issues at Bath, in the database and in Walker's own SE Corpus (the Croydon hoard and other sites), were all still much larger than the 1.5% representation on the Continent, so the British association is still maintained. Similarly with the other two. However, the association of one issue with Britain may be questioned: the FORT RED asses of Hadrian. Walker (1988,190-1) shows that this issue comprised 14 out of 24 of the *asses* at Bath, whilst only 5 of 64 from the continent (58% against 7.7%). However, this is only the case if all the Britannia coins are excluded from the count. If they are included then the proportion at Bath is 7.2%, in the site-find database 8.2% and on the continent 7.8%.

That is to say the proportion of FORT RED coins in Britain is not noticeably different from that on the continent, and its claim to be a coin principally directed towards Britain must be rejected.

Table 4.22: Issues with particularly British distributions.
Bath, SE Britain and Continental data from Walker 1988, Database information from the thesis.

		Bath		Database		SE Britain		Continental	
		No.	%	No.	%	No.	%	No.	%
HADRIAN									
Asses	RIC 577 (Britannia)	39	*20.0*	8	*16.3*			1	*1.5*

AE2	RIC 1317	12	*11.6*	1	*5.6*				
	RIC 1322	61	*59.2*	3	*16.7*	14	*77.7*	0	*0.0*
	All identified AE2	103	*100.0*	18	*100.0*	18	*100.0*	93	*100.0*

Note: Clay's (1988,223) correction to Walker's table (1988, 294 col 1) is wrong. Walker's figures are correct.

The Hadrianic and Antonine supply figures

With the identification of several issues which specifically circulated in Britain, Walker opened up the possibility of reconstructing *aes* supply figures for the province. The argument goes as follows: die link analysis can estimate the original number of coins of each issue minted. If a province specific issue represents a known proportion of site finds, and if its issue size can be established, then the two values can be used to calculate the total issue of that period. Walker did this for the Hadrianic and Antonine periods based on die link analyses of the issues referred to above.

In the following Walker's calculations are shown together with a recalculation on the basis of the site find database instead of the Bath coin list. The aim is to show the possible variation in Walker's results by using a different assemblage to scale up the die-link analysis figures.

Hadrianic period calculations:

Die study figures calculated using the value of 20,000 coins per obverse die:

Issue	Date	No. at Bath	Issue size	No. of coins represented by 1 coin at Bath
Hadrian's Britannia Asses	AD 128	39	352,000	9,025
Hadrian's Salus Asses	AD 128	52	823,400	15,834
Combined	AD 128	91	1,102,200	12,112

	at Bath	in Database
Fully identified Asses of Hadrian & Sabina:	221	53
Number of Britannia & Salus types	91	13
Proportion of Britannia & Salus types	41.18%	24.52%
If X % of the issues represent 1,102,200 coins in circulation in Britain, then all of Hadrian's issues amount to:	2,676,000 asses	4,495,000 asses

As can be seen the variation between the Bath list and the Site Find database is substantial. In order to gauge the credibility of these a third assemblage can be examined: that from Coventina's Well. This list contained about 54 to 117 identified *asses* . The range is due to the presence of 63 coins which may either have been *asses* or *dupondii* . Since 22 of them were Britannia and Salus types this means that the proportion represented by them was somewhere between 18.8% and 40.7%. Presumably the actual value is somewhere between the two. This is similar to the range given by the Bath and Database figures of 41.1% and 24.5%. So Walker's figure can be taken to represent a minimum figure for the number of Hadrianic *asses* sent to Britain (working on the assumption of 20,000 coins per obverse die).

Antonine period calculations:

Issue	Date	No. at Bath	Issue size	No. of coins represented by 1 coin at Bath
Antoninus Pius Dupondii	AD 153-155	69	409,000	5,927
Marcus Caesar Dupondii	AD 153-155	19	360,000	18,947
Antoninus Pius Asses	AD 153-155	219	1,756,000	8,018
Marcus Caesar Asses	AD 153-155	54	280,000	5,185
Faustina I AE2	AD 153-155	73	828,200	11,345
Faustina II (A.P.) AE2	AD 153-155	33	350,600	10,624
Combined	AD 153-155	467	3,563,600	7,630

ISSUES OF ANTONINUS PIUS	at Bath		in Database	
	Dupondii	Asses	Dupondii	Asses
Ratio of Dupondii to Asses (all British circulation coins)	97	370	19	39
If these represent 3,563,600 coins, then there are: (Y)	740,191	2,823,408	1,167,386	2,396,214
Total number of fully identified coins	214	514	68	103
Proportion of fully identified coins: (X)	45.32%	71.98%	27.94%	37.86%
If X % of the issues represent Y coins in circulation in Britain, then the total number in circulation = 100Y/X	1,632,998	3,922,247	4,178,013	6,328,462

Again the Site Find database assemblage suggests a higher figure than the Bath coin list, possibly of the order of doubling Walker's figures. It must be noted that the site find database represents a much smaller sample that the Bath list, however, it is not as obviously composed of deliberate votive offerings as the Bath deposit. It may be that some of the coins with 'British associations' were preferentially deposited at Bath. Such questions cannot be answered without the compilation of an even larger database of site finds.

The two sets of calculations above have estimated the number of Hadrianic *asses* , and Antonine *dupondii* and *asses* in circulation in Britain. Walker then extended these values to estimate the number of other denominations of each period:

NUMBER OF COINS IN CIRCULATION IN BRITAIN		Dupondii	Asses	Sestertii	TOTAL
Hadrian	Calculated figures (see above):		2,676,000		
	Proportion of denominations at Bath:	316	319	368	
	Estimated original population:	2,650,833		3,087,047	
	Valuation in sestertii:	1,325,416	669,000	3,087,047	c.5,080,000 HS
Antoninus Pius & family	Calculated figures (see above):	1,632,998	3,922,247		
	Total number of all dup. or sest. at Bath:	462		499	
	Estimated population of sestertii:			1,763,779	
	Values in sestertii:	816,494	980,561	1,763,779	c.3,560,000 HS

Note: The number of *sestertii* is estimated by using the ratio of *dupondii* at Bath to their proposed number in circulation. Therefore (1,632,998 x 499)/462=1,763,779

The figures achieved by Walker may have to be scaled upwards, however, the broad result that the Hadrianic input of *aes* coinage was larger than the early Antonine input should be accepted; especially considering Antoninus Pius' reign was slightly longer.

Walker went on to look at the proportion of Hadrianic and early Antonine coins in hoards to estimate the total coin population in Britain, however, since the bronze hoards are of various denominations and the estimated issue sizes already subject to huge margins of variation this will not be pursued, except to say that his ranges of the order of magnitude may similarly have to be increased from 10-15 million HS to 10-30 million HS in the late first century.

4.22 The supply of *sestertii* : method I

The question of the supply level of *aes* to Britain will now be tackled in a different manner, by using the same model established in section 3.2. The results will then be compared with Walker's analysis and other data (Section 4.23).

With *aes* in Britain we have three principle denominations, *asses* , *dupondii* and *sestertii* . In order to create a model for the supply of each of these to Britain it is necessary first to construct a cumulative composition curve showing the changing composition of hoards from the mid first century through to the late third.

The details of the composition of *aes* hoards are given in appendix 2.24. Unfortunately only the brass *sestertius* provided enough sample hoards to give a systematic picture. Figs. 43.04-06 show the construction of this curve with two example cumulative composition curves and the over-all picture. The data for fig. 42.06 is provided in Appendix 4.21. This picture has then been combined with the *sestertius* data from the site find database in the same way as the *denarius* bench-mark and site find data were

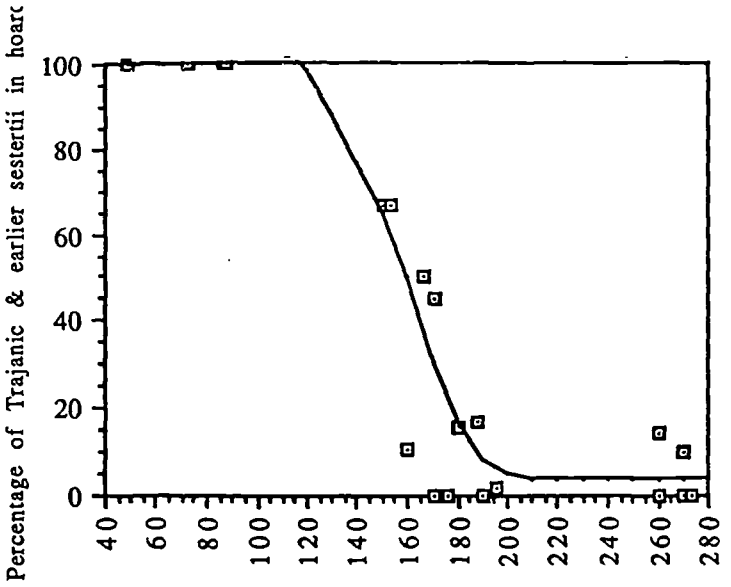

Fig 42.04 The proportion of *sestertii* up until Trajan in British bronze hoards

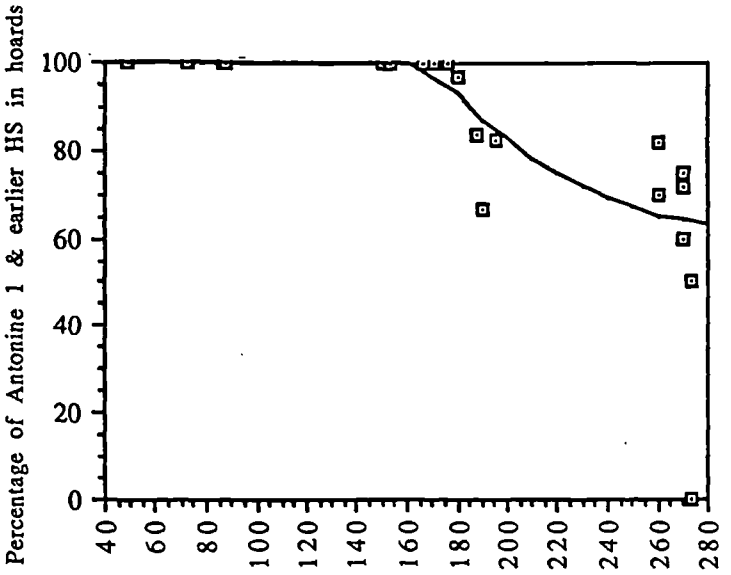

Fig 42.05 The proportion of *sestertii* up until Antonine 1 in British bronze hoards

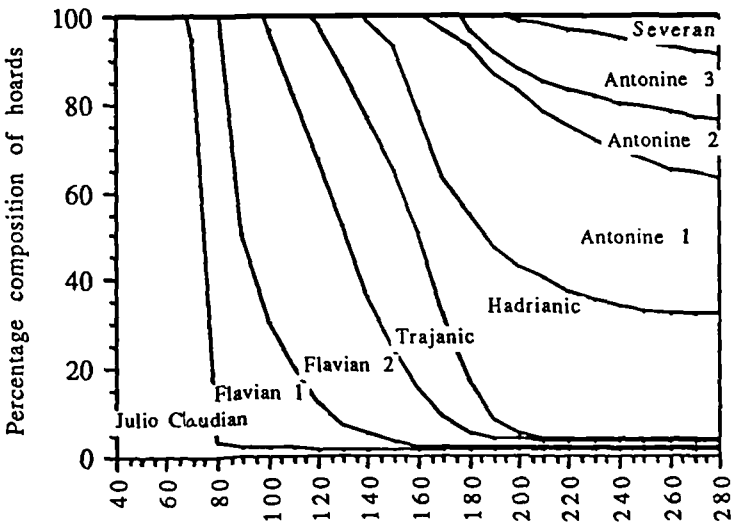

Fig 42.06 The make-up of the *sestertius* supply pool

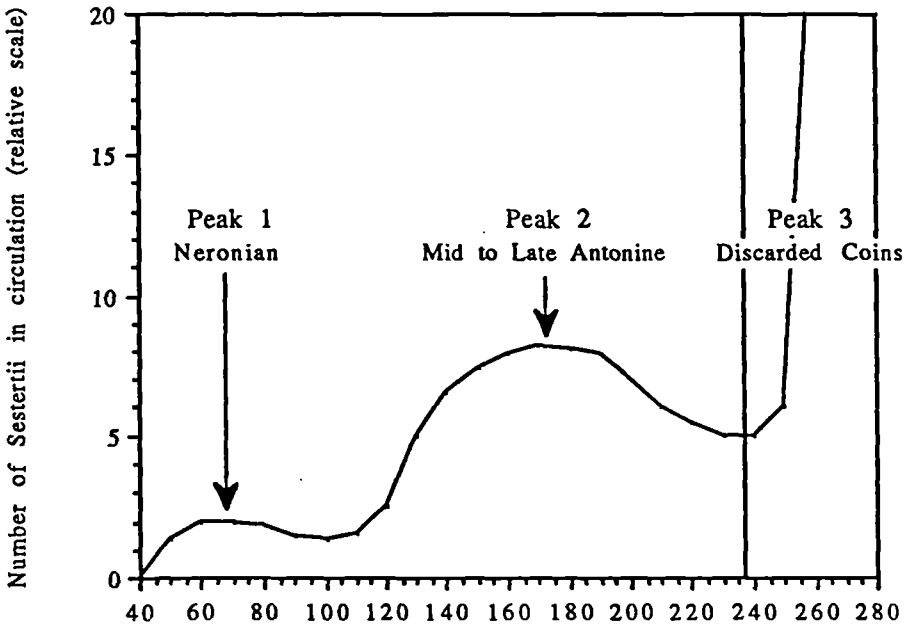

Fig 42.07 *Sestertius* supply curve I

combined (Section 3.3). However, since the number of *sestertius* hoards was relatively small, instead of calculating a curve at five year intervals, 10 year intervals have been used. The result is provided in fig. 42.07, the data for the shape and the site find database input values are provided in appendix 4.22.

The model is much coarser than the previous one for the *denarii* due to the lesser quality of the hoard data. The principle features are as follows:

1. A peak in the Neronian/Early Flavian period

2. A second peak reaching its zenith c. AD 170.

3. A third peak in the late third century, much higher than all the others.

The first peak tallies with the suggestion that the Bath report had under-represented the number of Julio-Claudian and early Flavian coins.

The second peak is the result of a continued increase in the number of *sestertii* around from the start of the second century until Marcus Aurelius. This is when we have at our disposal Walker' estimates for the number of new issues arriving in the province. He suggested that 3,087,047 HS arrived under Hadrian (= c.147,000 HS p.a.) whilst 1,763,779 HS arrived under Antoninus Pius (= c. 76,000 HS p.a.). This suggests that during the reign of Hadrian (117-138) the rate of increase in the *sestertius* circulation pool should be about double that in the Early Antonine Period (138-161). This is indeed the case. Walker's die link study therefore provides some corroboration for this part of the curve.

The third peak is rather a different matter. This takes place after *sestertii* ceased to be sent to the province, and yet the model demands some reason for the increased deposition of old *sestertii* in the late third century. The answer probably lies in the context of the collapse of the *denarius* monetary system in the third quarter of the third century. Along with the collapse of a monetary system comes the possibility of the deliberate discard of now worthless coin. This is how this peak should be seen, rather than a reflection of the total number of *sestertii* in circulation. A second context for their discard may have been the monetary reforms of Postumus (259-268) who issued very large numbers of new sestertii in Gaul, though few were ever to reach Britain (Bastien 1967). Perhaps some enactment of his may have demonetised these earlier *sestertii* resulting in their deposition on sites.

4.23 The supply of *sestertii* : method II

When dealing with bronze coin rather than silver or gold, another means lays at our disposal to try and reconstruct supply figures, or at least a relative idea as to how supply levels fluctuated. When gold and silver coins went out of circulation we may assume some were lost whilst the majority would have been melted down, either by the issuing authority recycling coin or else by individuals. With *sestertii* , however, what would be the consequences of assuming that all these coins were lost from circulation and none were recycled or deliberately discarded? The assumption is flawed since many *sestertii* were probably deposited in the third century when the monetary system fell apart, or else recoined as Barbarous Radiates. However, as an exercise it is worth pursuing.

If all *sestertii* were 'lost' from circulation, then the total number of site finds should accurately reflect the number of coins originally in circulation. We can use this idea to model the number of *sestertii* of an emperor (eg. Hadrian) in circulation at any one time. There were 234 HS of Hadrian recorded in the database. We can make two working assumptions: first that most of these would have come into circulation during his lifetime, and secondly that their issue was spread out evenly throughout his reign. These assumptions are almost certainly not true, however, the kind of broad changes being investigated here are of a slightly larger magnitude than the length of a single emperor's reign, so these need not worry us too much. Fig. 42.08 (Curve A) shows the number of these coins steadily increasing as they are issued from the mint, from zero at the start of his reign to 234 by his death. Thereafter the number declines as they start to get lost. Here an arbitrary wastage figure has been set at 2% of the coin stock p.a.. Of course this is not strictly accurate, coins would have started to be lost immediately after the first issue, not after the end of the final release. So curve B shows this factor taken into account as well. So we can model the number of *sestertii* of a given emperor in circulation given an assumed wastage rate. The wastage rate may be modified, and the same example is repeated in Fig 42.09 at rates of 2% and 4% p.a..

By doing this for all the *sestertius* issues found in Britain we can add them all up and come to a hypothetical *sestertius* supply curve, or rather a series of them depending upon which wastage rate seems most likely or acceptable (figs 42.10 & 42.11; Appendix 4.23).

The most notable features in these curves are the repeat as before of the mid second century peak, and at wastage rates of 8% and above the appearance of a second peak very shortly after the Roman conquest of the south-east. This compares favourably with the peaks suggested by the first method used in section 4.22.

4.24 The hoarding of bronze in Britain

The first *sestertius* supply curves could be corroborated during the first half of the second century by David Walker's results. The final peak was also explicable in terms of the decline of the *denarius* monetary system and the deliberate discard of the coin. However, no supporting evidence has yet been advanced for the early peak apart from its reappearance using a slightly different method to reconstruct supply figures. However, support can be found by a different kind of analysis of coin hoards.

By a cursory look at comparative material, Britain appears to have far fewer bronze and mixed hoards than can be found in France and elsewhere in the empire. Whilst this might be a function of the degree of development of the LPRIA societies at the time of the Roman conquest (cf Section 4.1), it might also be due to a problem of supply to the province. In order to investigate this matter all the hoards in the corpus were divided into three categories: those containing only precious metal coins, those containing only *aes* coins, and those containing a mixture (in whatever proportions). These were divided up into ten year blocks depending upon their latest coin (Appendix 4.24). The resulting pattern is shown in fig. 42.12. On the left are shown the total number of hoards, whilst on the right the same data is shown as a proportion of all hoards in that ten year block.

The important features of the pattern are that during the main lifetime of *aes* in Britain, *aes* only and mixed hoards were most frequent in the AD 40-80s and the 140-190s. There are troughs around the turn of the first second century and in the early third century. This pattern matches directly the proposed *sestertius* supply curve.

It is concluded that the occurrence of *aes* and mixed currency hoards goes some way to substantiating the *sestertius* supply curve generated in section 4.22. *Aes* and mixed currency hoards were most commonly assembled when *aes* formed a larger part of the circulation pool from which to draw it.

4.25 Multi-metallic systems

The discussion of mixed hoards leads us onto the question of multi-metallic coinage systems. In the LPRIA the earliest coinages were in precious metals, followed by potin and bronze. Each has been argued to have a specific function, partly revealed in the differences in the distribution pattern of each. Gold may have been used for intertribal exchanges, with limited other functions, whilst potin may or may not have been 'special purpose money' for circulation within the tribal area in different forms of transactions

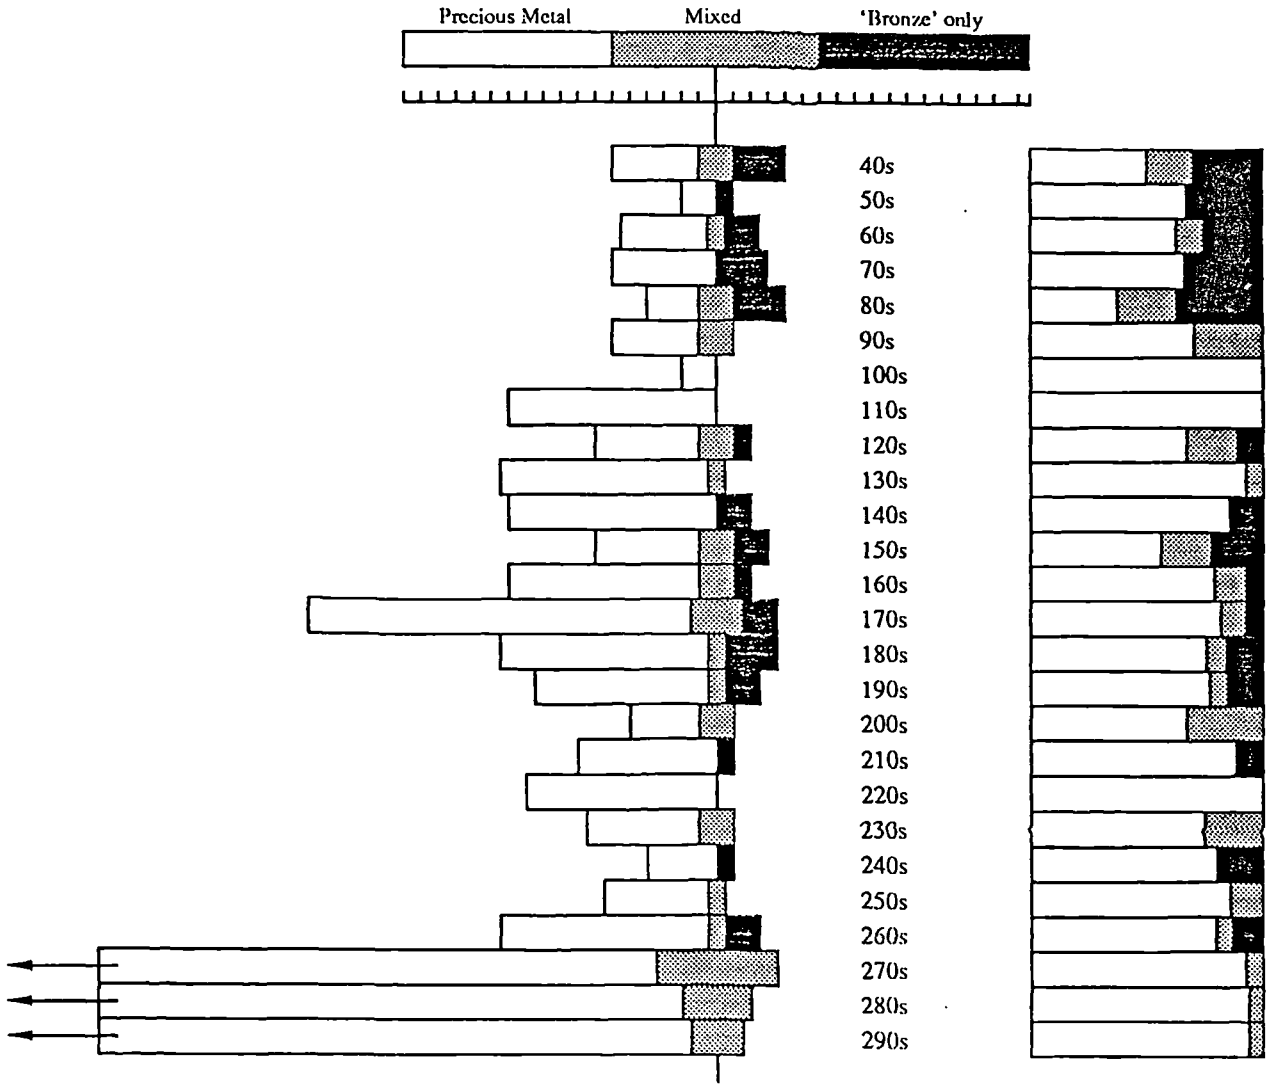

Fig 42.12 The hoarding of bronze and silver

(Haselgrove 1979, 207). The precise nature of these different functions may be difficult to reconstruct, but that there were such divisions has been generally agreed.

In contrast the Roman monetary system in the late Republic and Early Empire has usually been discussed in terms of a unified system, illustrated in the Augustan reforms, despite the origins and subsequent development of Roman coinage. In origin the use of silver and bronze was quite different. Silver developed from the usage of the cities of Magna Graecia, possibly largely to pay mercenaries and transactions with other cities; whereas Roman Bronze currency developed from the totally different origins of *Aes Grave* and *Aes Signatum.* Only in the third century BC did these elements start to come together with the establishment of theoretical numerical relationships between the two (Burnett 1987). Similarly 4th century AD coinage is typified by a division between bronze/billon coinage and precious metal coin. Precious metal was the coin of state payments and taxation, whilst bronze coinage was the coin of the market. Nonetheless despite a functional difference the two had at various points fixed relationships to each other.

The origins and subsequent history of Roman coinage show how one might still have dual systems running within what might superficially appear to be a unified currency system. So how unified was the Augustan system ? We know that in the Hadrianic period *denarii* and bronze issues were certainly not circulating in a rigid system of 16 *asses* to the *denarius* . In Pergamum a judgement is recorded in an inscription which tells us *denarii* were bought and sold by money-changers for 17 and 18 *asses* respectively, and that transactions on the fish stall had to take place in bronze coin or else a surcharge would be demanded (Burnett 1987, 102). If the values had been just above and below the notional value of 16 *asses* then this would tell us nothing more than the money-changers were charging a commission on the exchanges. However, they are not. Unless the local relationship between *asses* and *denarii* is of the order of 17.5:1 then the money-changers would be making a loss on one transaction or other, and this would be most out of character. Even if this inscription refers only to the autonomous bronze coinage of Pergamum it shows flexibility within what on the surface would appear to be fixed denominational relationships.

If market transactions had to take place in *aes* , then this effectively acted like a sales tax. All transfers between the precious metal (the medium of the storage of wealth) and bronze coin (the medium of the market place) would have taken place with the assistance of a money-changer, profits being accrued on each transaction.

> "A commission was made on these exchanges, as it is by banks today. The profit made in this way, however, did not just benefit private corporations, since the moneychangers operated under official control and

> either purchased the right to their position or passed on their profits to the licensor (normally the city in which they operated). A commission was also charged on their other main activity, changing coins from one metal into those of another, and the profit made on such transactions was a constant source of aggravation."
>
> (Burnett 1987, 102)

If this did happen everywhere it might help explain two phenomena. First, if bronze was the coinage of the market place, whilst stored wealth was usually kept in silver and gold, it explains why in the first to third century there is relatively less bronze coin found on rural sites in Britain. Precious metal coinage would only be converted into bronze coin when transactions at the market were called for. Similarly profits from trading in the town may have been converted back to the medium of storage, *denarii* , before returning to the countryside.

Secondly, if this dual system provided a revenue for the local administration, then the decline of the use of bronze due to the debasement of the *denarius* and *antoninianus* may have resulted in a decline in income of the *civitates* . A uni-metallic system would derive no such income for the towns of the provinces. This may have been an additional factor in the Empire as to why the investment in and maintenance of public buildings declined from the late second century onwards, and why the state increasingly needed to send in *curatores* to sort out city finances (Garnsey & Saller 1987, 34). If Blagg's (1990) interpretation of the building inscriptions from the NW provinces is correct then munificence in Britain relied far more upon the civitas as a corporate institution than on individuals competing for civic office. So if civic income fell due to the decline of money-changing then so may have its capacity to maintain public buildings; but of course this is entirely wild speculation.

4.3 The debasement of the *denarius*

Prevailing views of the concept of debasement are discussed (4.31). A study then relates the amount of silver circulating in the currency pool to the issuing standard at the mint (4.32-33). Variability in the quality of newly issued denarii is discussed in relation to bullion supplies and quality control (4.34), and finally a primary link between the rate of wear of the denarius in circulation and its debasement is made (4.35).

4.31 The classical view

Not only was the structure of the circulation pool ever changing, but so was the composition of the *denarius* itself. The fact that the *denarius* was debased has arisen many times in the preceding discussion, but here I wish to question exactly what debasement was and what it meant to imperial finance; the simple answer - a nice healthy profit - is surprisingly not the one concluded. In the Republic and early Augustan period the *denarius* was made of good silver, over 96% fine. This high value had remained remarkably constant for a long time. The analyses of Republican coins from the mid second century BC to P. Clodius (42 BC) all have a correspondingly high value. Only with Mark Antony did standards slip significantly (Crawford 1974). The first substantial debasement came with Nero's reforms, followed progressively more frequently by further adjustments until the coin contained less than 50% silver and was supplemented by, and eventually replaced by the *antoninianus* .

The broadest work quantifying this process are Walker's metallurgical analyses (1976, 1977, 1978). A summary of his results is provided in Appendix 4.31. The two principle variables he established were the silver content from XRF analysis (which suffer from some unsystematic errors, though the broad picture can be accepted) and a guide to the weight of the coins. Walker interpreted the evidence as a step-wise series of carefully controlled reductions (raw data: fig 43.01; Walker's interpretation: fig. 43.11). However, we must remember that this is only one of the possible interpretations of the data. Certainly the weight of silver in the coins fell, but an examination of the single standard deviation error bars suggests that the real picture might have been a bit more blurred than Walker's interpretation suggests. These error bars only represent variation due to the alloy content, if the variation due to the weight of the newly minted coins were also taken into account as well the error bars would be even wider. Even so, the more prominent reforms such as the debasement by Nero, and Domitian and

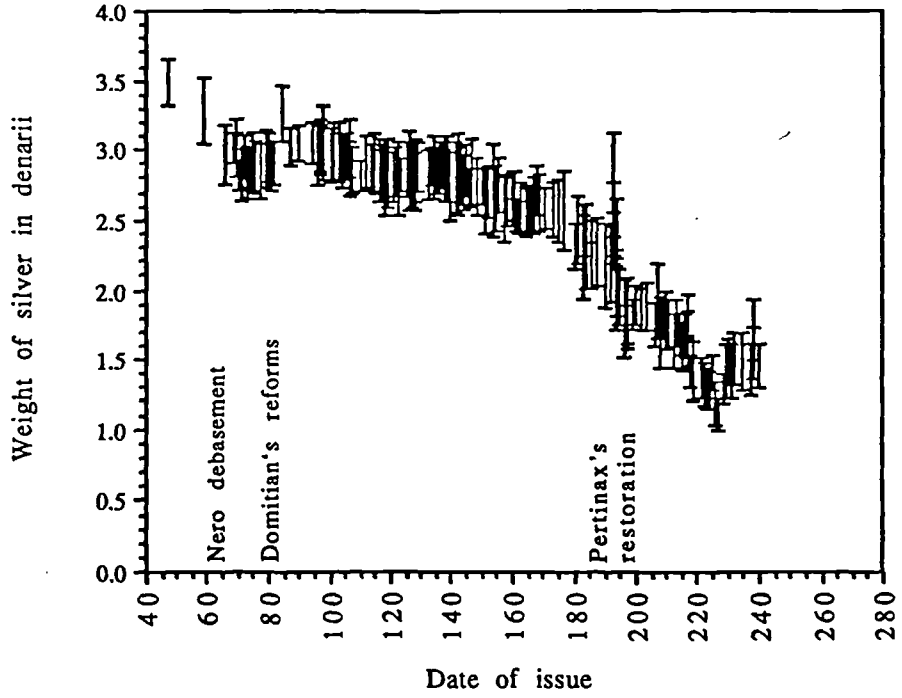

Fig. 43.01 The metrology of *denarii*: silver content

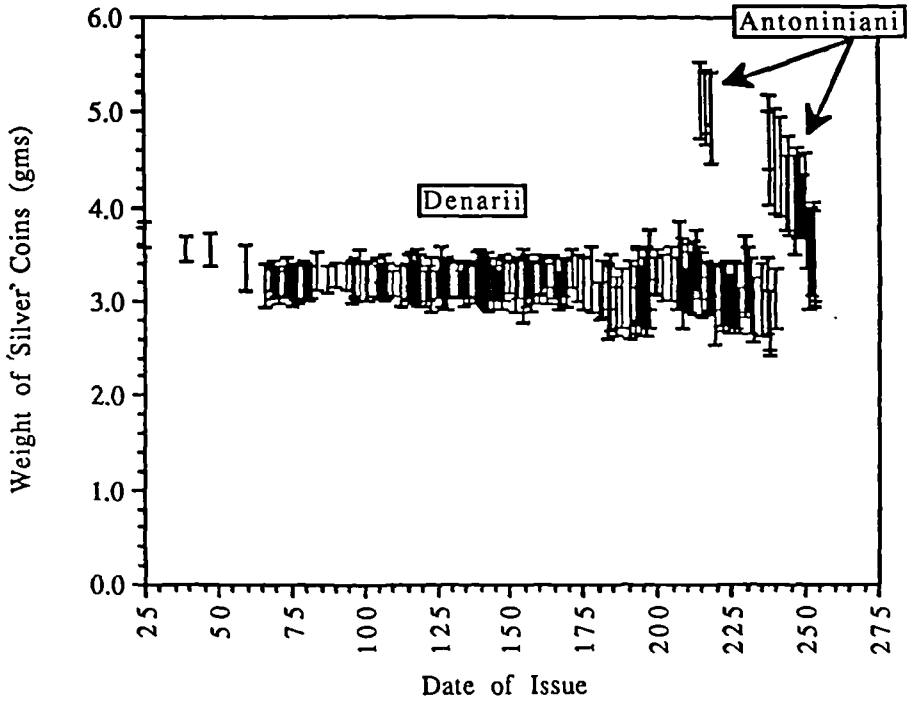

Fig. 43.02 The metrology of *denarii*: weight

Pertinax's short lived improvements, show themselves clearly. The weights (as far as the original minting weightscan be assessed) on the other hand, appear to be maintained quite well, though a slight decline in the late second to early third century can be noted (fig 43.02), however, again this change is well within the one standard deviation margin of error.

Walker (1978) interpreted the pattern in the light of the perceived fiscal policies of each emperor, described in terms of *avaritia, liberalitas* and *parsimonia* ; greed, generosity and frugality. Where as more money could always be raised by taxation or the confiscation of property, this was unlikely to make an emperor friends:

> "The anxiety which every emperor felt to be able to spend money freely without having to increase taxation (therefore not only displaying *avaritia* but also, on a more realistic level, risking unpopularity with the groups taxed) made debasement of the coinage a particularly attractive way of increasing imperial spending power, while avoiding criticism. ...debasement took place almost invariably with this end in view..."
> (Walker 1978, 109)

The assumption has always been that debasement made a short term profit for the mint: "Quite simply, old *denarii* collected in taxes could be melted down to make a larger number of new, less pure, coins, which would go further for paying the army and civil service." (Greene 1986, 61). This belief however requires testing; debasement need not have made a profit at all.

4.32 The reality of the circulation pool

At this point I want to turn away from the historical interpretation of the data and examine some of the basic ideas underpining our concept of debasement. To do this a simple model of the circulation and reminting of coin is put forward. Then slowly other variables are taken into consideration leading to complications in the picture. This model examines the implications of the recycling of coin, the degree to which this actually took pace will be discussed at the end.

Reminting silver: the ideal cycle (fig. 43.03)

In the simplest of all worlds *denarii* would be issued at a set weight, containing a certain quantity of silver. If the old Emperor died the new one might wish to see new *denarii* issued with his face on them, instead of that of his predecessor. 100 *denarii* are called in to be reminted and 100 new ones produced, at the original weight, with the same amount of silver in them. Here reminting is simply a symbolic and political expediency, spreading the image of the new emperor to all his people. Otherwise reminting has no function. No profit is gained. In fact it costs the emperor money for

all the labour involved. This of course is not a real situation, but it serves to introduce one to the more developed models put forward below.

Reminting silver: the classical model (fig. 43.04)

Now let us turn to look at the classical view of debasement. The idea is that by adulterating the alloy with a supplement of base metal it would be possible to make the silver at one's disposal go further, thereby producing more coins but of a lower standard. If 100 coins of one silver content were called in and 110 produced, this would make a short term profit of 10 *denarii* per 100 recycled so long as the public accepted the coin. Such dilution of an alloy by recycling has been demonstrated in other coins such as *sestertii* (cf. Étienne, Rachet et al, La Trésor de Garonne, 1984).

Reminting silver: the effect of coin wear

Unfortunately this model lacks a fundamental variable which needs to be added into the equation: coin wear. The coins which came back into the mint were much lighter than when they had left many years before. This we established in section 2.3. This means that if 100 worn coins come in from circulation, then unless any further metal is added to the melting pot it would be impossible to create 100 new coins of the same weight. So unless the alloy is tinkered with the mint will slowly produce fewer and fewer coins and therefore make a loss. This is demonstrated in fig. 43.05. This cycle can be used to explain why Republican coinage was rarely minted during the later Republic:

> "Why would the Roman mint systematically take in partly worn old coins, of almost pure silver, and remint heavier newer coins of the same purity ? By doing this, the mint would shoulder all the cost of wear and of reminting. The answer depends partly on the fiduciary element in the currency, on how far the coins were valued above their silver content, and on the availability of silver bullion"
>
> (Hopkins 1980, 107 note 19)

Reminting silver: composite model, debasement by default (fig. 43.06)

The alternative to adding bullion is to make up the weight lost due to wear, is to make up the deficiency with base metal. The philosophy behind this would be that maintaining the weight of the coin retained its credibility more than lowering its weight while maintaining the alloy standard. It is easy to tell if a coin is under-weight, it is not so easy to tell if a coin has 87% silver or 86% silver. Here the coin could be recycled without making a loss, but a consequence would be a decline in the silver standard.

The main point of this exploration is to show that because silver was lost in the circulation pool due to coin wear, if they were called in and reminted then debasement would be an inevitable result, unless the mint were to make a loss. These considerations also suggest the rate of debasement might be directly related to the degree of wear

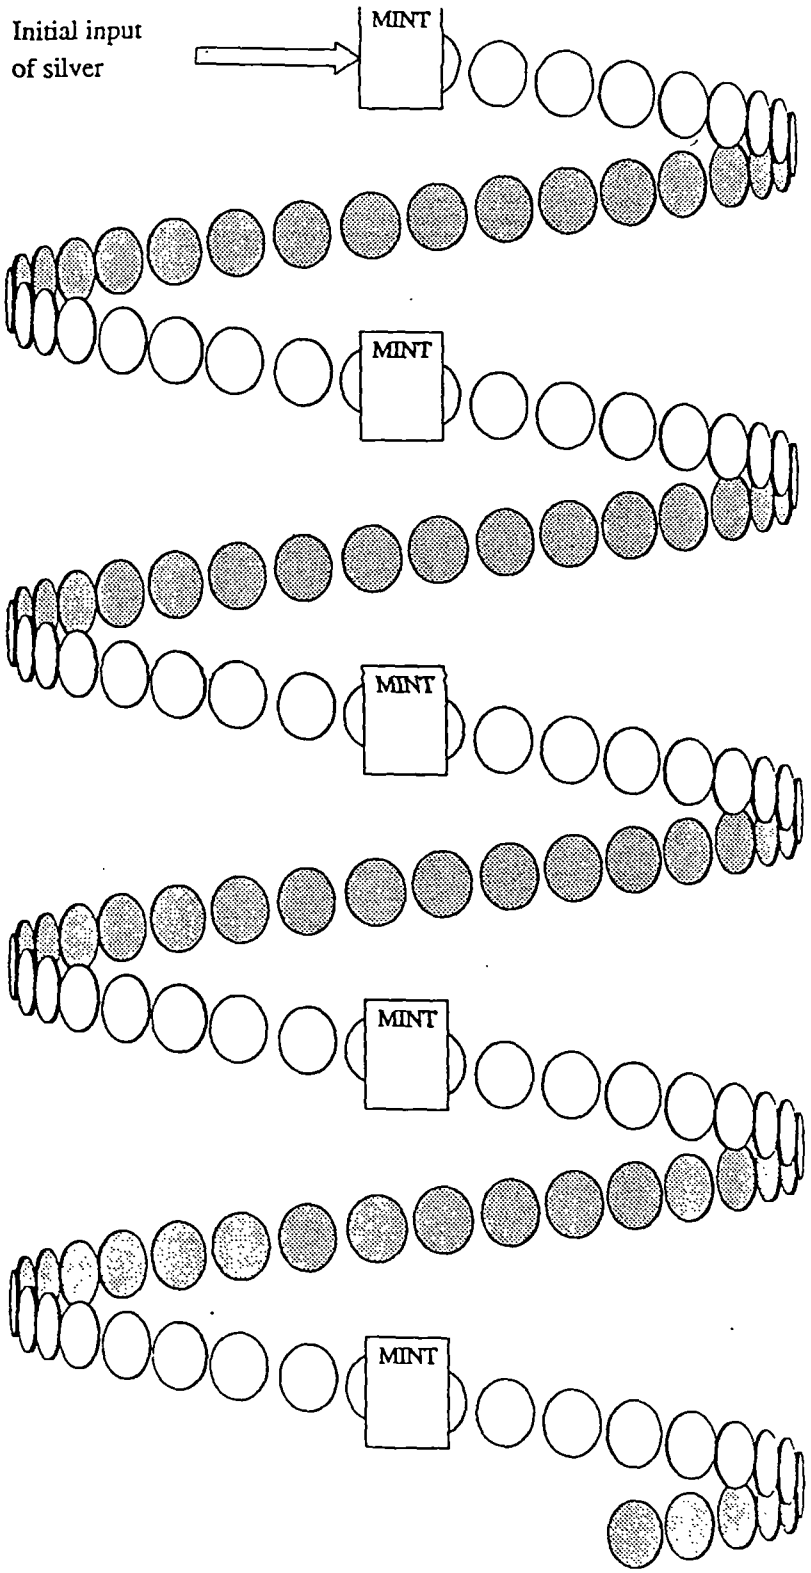

Fig. 43.03 Reminting silver: theoretical model

The original silver standard and weight are manitained. Coins withdrawn from circulation are totally unworn. There is no loss of silver in the minting process.

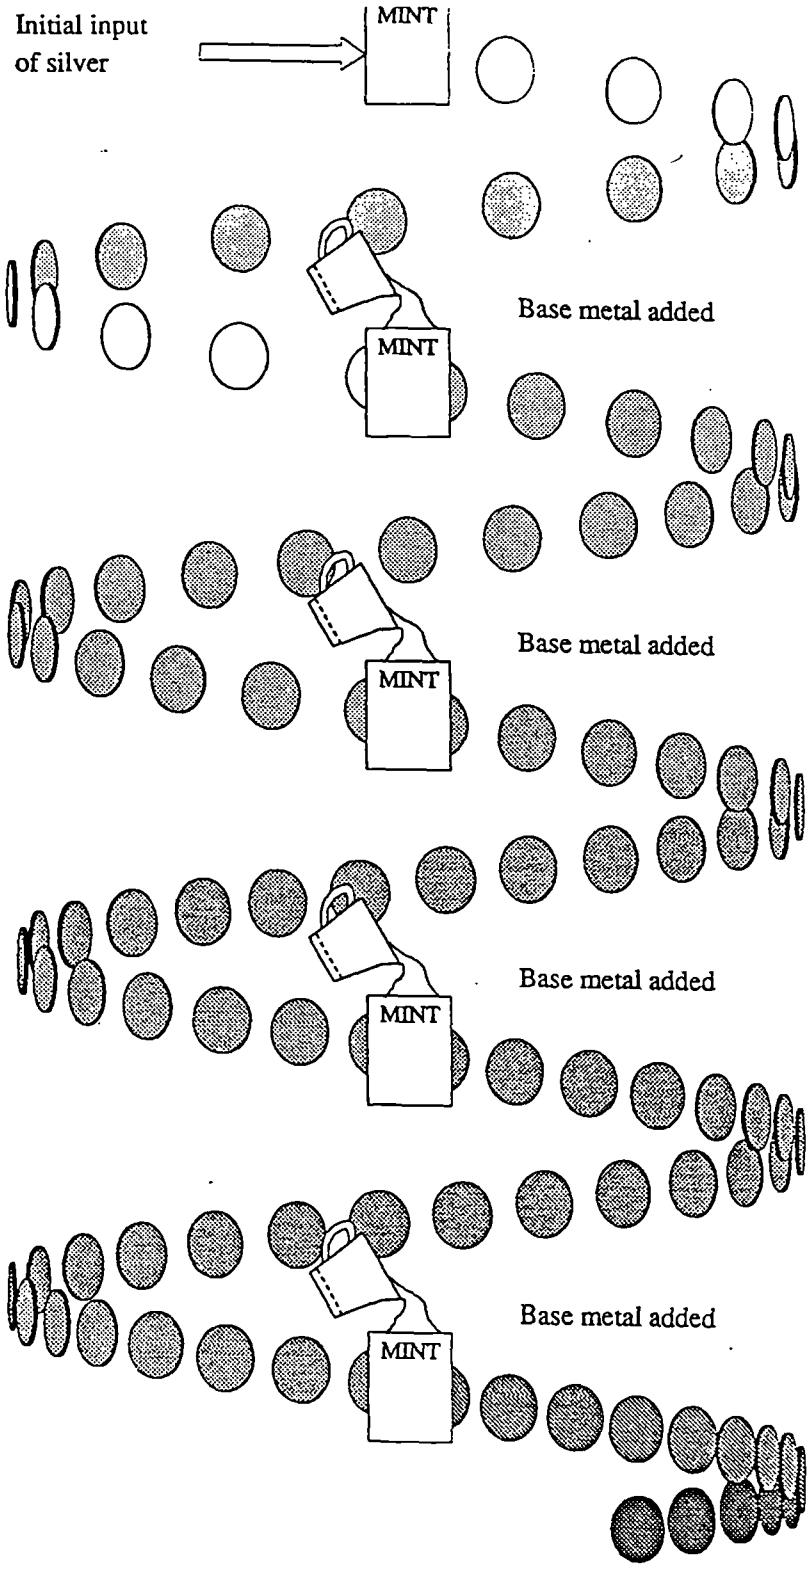

Fig. 43.04 Reminting silver: classical model

The coins called into the mint are melted down and base metal is added so that additional coins can be produced while still maintaining the full weight standard. This means the mint makes a profit.

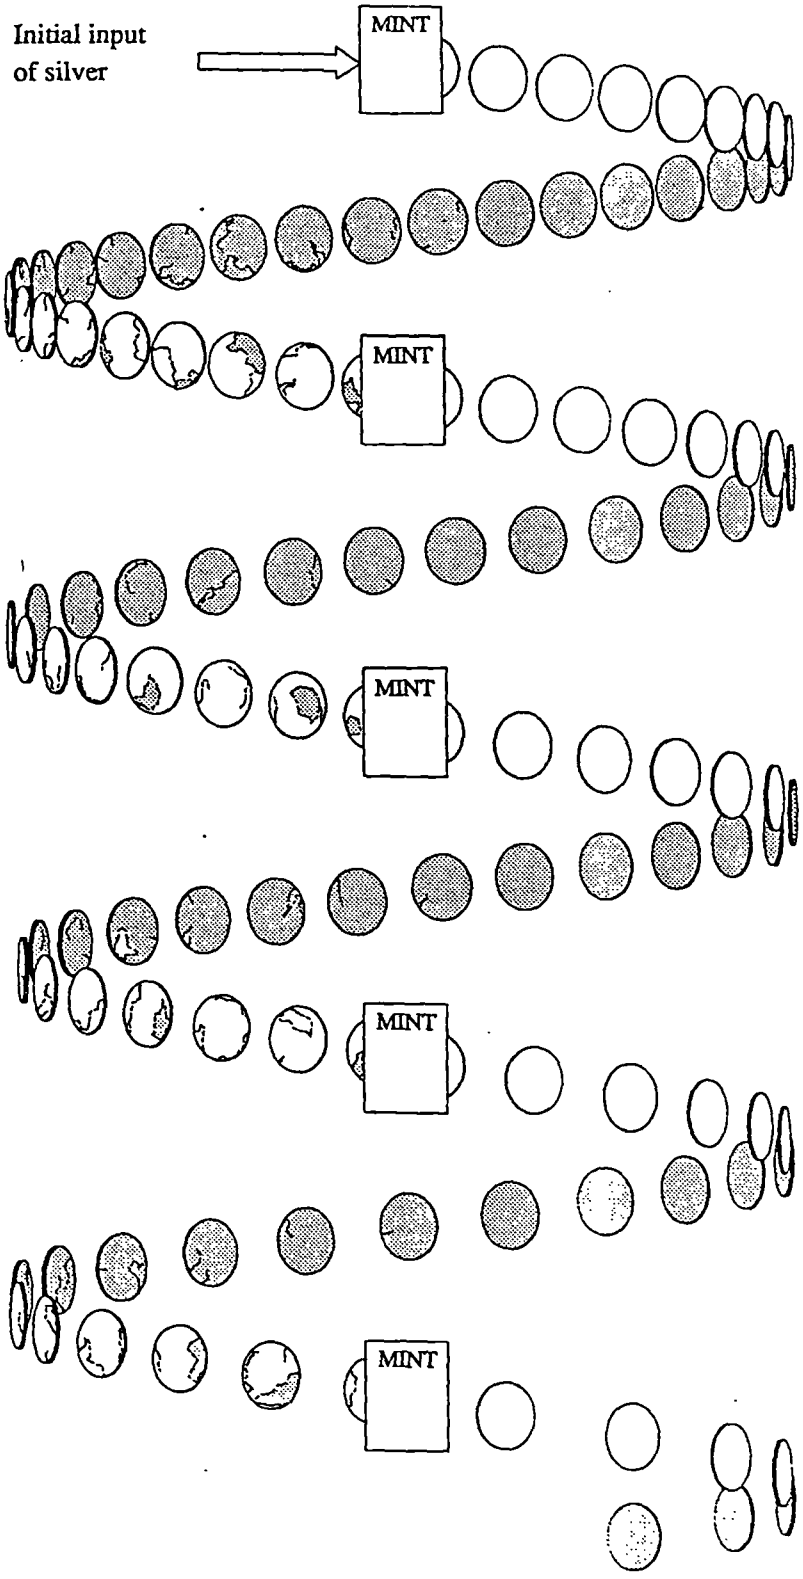

Fig. 43.05 Reminting silver: the effect of coin wear

The original silver standard and weight are maintained. However, because the old coin comes in under weight, fewer coins can be minted than are received. Therefore the mint makes a loss.

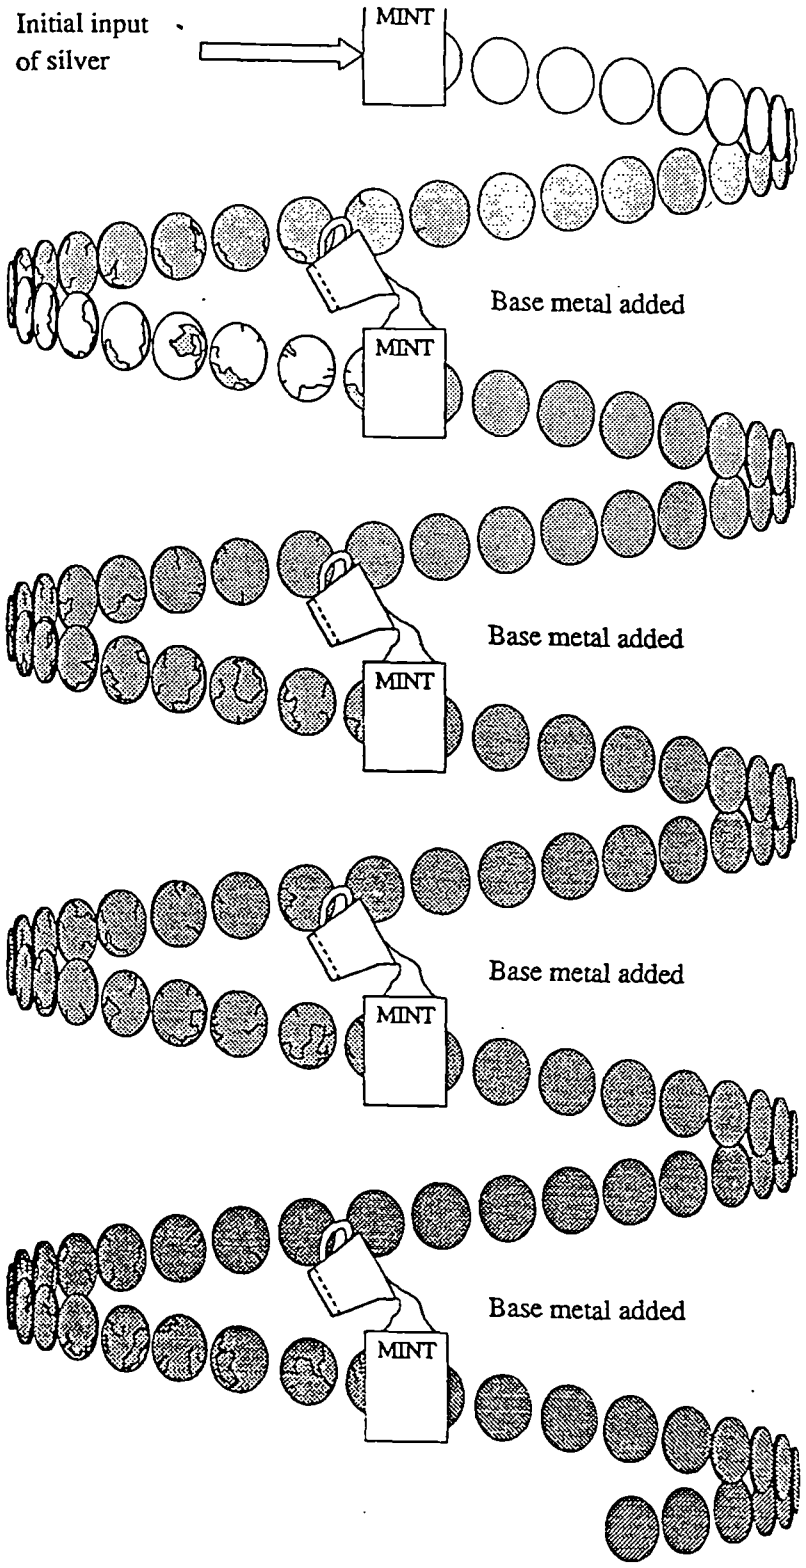

Fig. 43.06 Reminting silver: composite model - debasement by default

For every ten coins into the mint, ten are produced at the original weight standard. However, because of their worn state an additional metal supplement must be added to maintain the weight standard. This has the net effect of debasing the coinage.

taking place on *denarii* , all other things being equal. The reason why debasement only started in the very late republic is that until then coin was probably not recalled and reminted. This model *need not* mean the silver content of the newly issued *denarii* was not very carefully monitored and debasement took place in a controlled step-wise fashion; but it *does* run counter to the idea that debasement need have made a large profit for the exchequer.

4.33 Testing the model

How can this idea be tested? The theory predicts the following: if debasement was only the result of coin wear and not profit making, then the silver content of any new *denarii* from the mint at any date should be on average the same as that recovered by melting down a random sample of coins from the circulation pool in their various states of wear. What we need to do is establish values for these two variables. If similar then it would suggest that the hypothesis has some mileage in it.

We know the minting standards from David Walker's work (Appendix 4.31) so we have one of our curves. It is also possible to reconstruct the effect of melting down what is in the circulation pool. To start with we have quantified by our bench-mark the make-up of the mixed circulation pool (Appendix 2.42). We also know the percentage silver in each of those issues and their initial minting weight (Appendix 4.31). We have also calculated the rate of wear on these issues (Appendix 2.32). All this information combined together can tell us exactly how much silver would be recovered by melting down what was in circulation in Britain at any particular date.

The full calculations are given in Appendix 4.32. First the minting weights of each coin series are taken, these are then reduced by the rate of wear set for that particular date. This tells us the weight of any particular coin series at any particular date (Table 2). Then these values are multiplied by the percentage silver content of their respective issues and divided by 100. This tells us the weight of silver in a coin of any particular series at any particular date (Table 3). Finally these values are then added up in proportion to the number of coins of each series in circulation at any specified date (Table 4), to give us a value for the average silver content of a coin in circulation then. This is shown in fig. 43.07.

As can be seen the issuing standard of the day is more or less equal to the melt down content of worn *denarii* already in circulation. The correlation is fairly good. The most systematic deviation is from 150 onward where the mint appears to be producing relatively slightly more debased coins. So one could suggest that from this date debasement *may* have made a profit. However, compare the illustration with the error

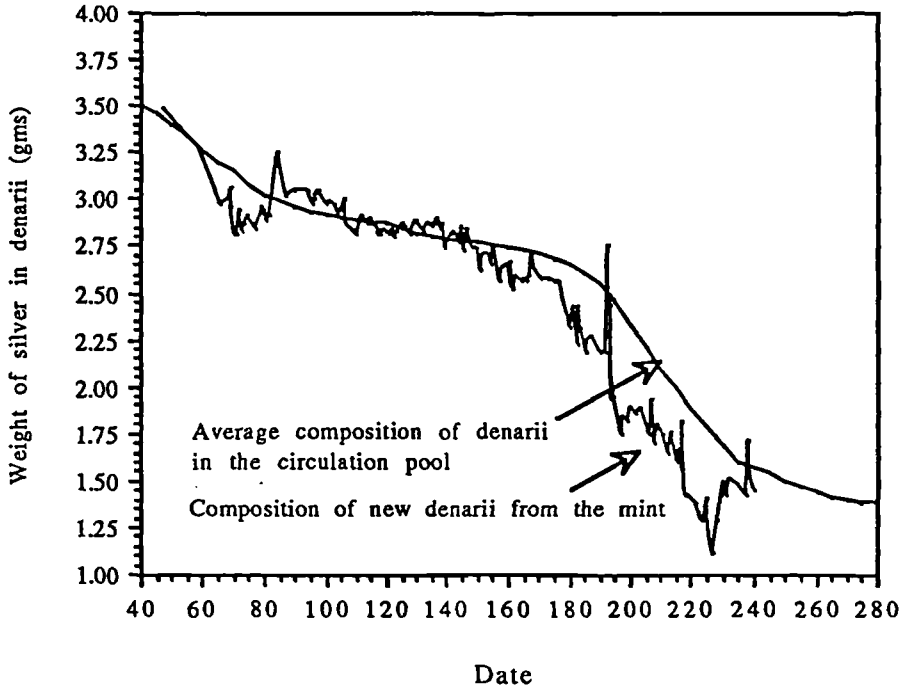

Fig. 43.07 The silver content of *denarii* from the mint and that of the circulation pool

bars in fig. 43.01 and the deviation appears to be much less significant than the variation in the composition in the *denarii* themselves.

4.34 Bullion Supplies and quality control

The alternative source of silver to recycled *denarii* is bullion. Even if bullion did make up a substantial volume of the silver supply for the new coin issued, it is unlikely that any issuing authority would have minted coins at a substantially higher silver content than their worn circulating counterparts. Had they done so it would have disappeared from circulation fairly rapidly. Such a problem was experienced by Domitian's early issues, where he 'improved' the minting standard briefly (Carradice 1983). Indeed Carradice specifically suggests that bullion was used for these higher silver standard coins:

> "...the increased standard of [Domitian's] silver cannot simply be explained as the result of a re-coining of earlier (Eg. Augustan) *denarii* of high fineness, because the consistency of fineness revealed by all pieces clearly denotes a coining of refined bullion."
>
> (Carradice 1983, 160)

The idea implicit in this statement is that we can tell the difference between periods of bullion dominating the mint supply and re-cycled coin being used by looking at the variation in the alloy of each issue. First one would need to establish how the consistency of the alloy varied, then this pattern would need to be cross checked against periods when bullion was known to be in large supply at Rome.

The figures for the variation in alloy composition again come from Walker's work (Appendix 4.31). The data are plotted in fig. 43.08. The consistency of Domitian's *denarii* can be seen to be substantially greater than in either the preceding or following period, and only matched by the issues of the Julio-Claudians. Otherwise the consistency of the alloy appears to deteriorate throughout the second and early third century, with perhaps signs of a marginal improvement during the 170-80s. Following Carradice's idea this might suggest that up until the Civil War there was a reasonable bullion supply, and as in the Republican period, most coin was adding to the circulation pool rather than recycling it. However, does this pattern relate to what we know of the dating of silver mines in the Empire?

The mines from around Carthago Nova in Spain were exploited by the Romans from the Republican period into the Empire (with a brief interruption during the civil wars), though work seems to have ended at the end of the second century (Keay 1988, 63). A similar pattern is suggested for the mines of the Sierra Morena. The mines of Río Tinto gained especial importance from the Flavian period, but production appears to have been disrupted late in the second century.

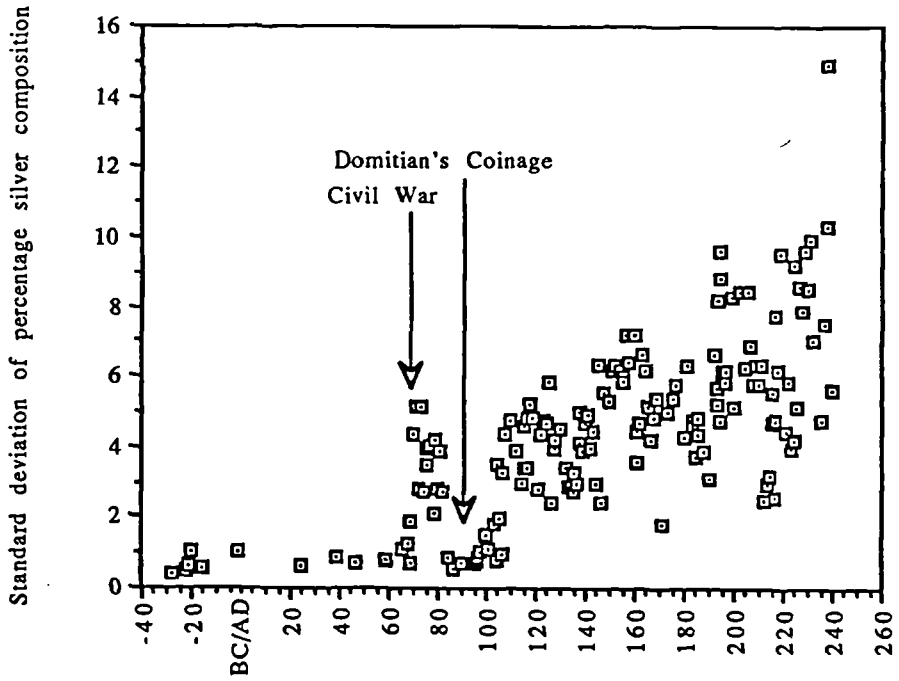

Fig. 43.08 The variability in *denarius* alloy composition over time

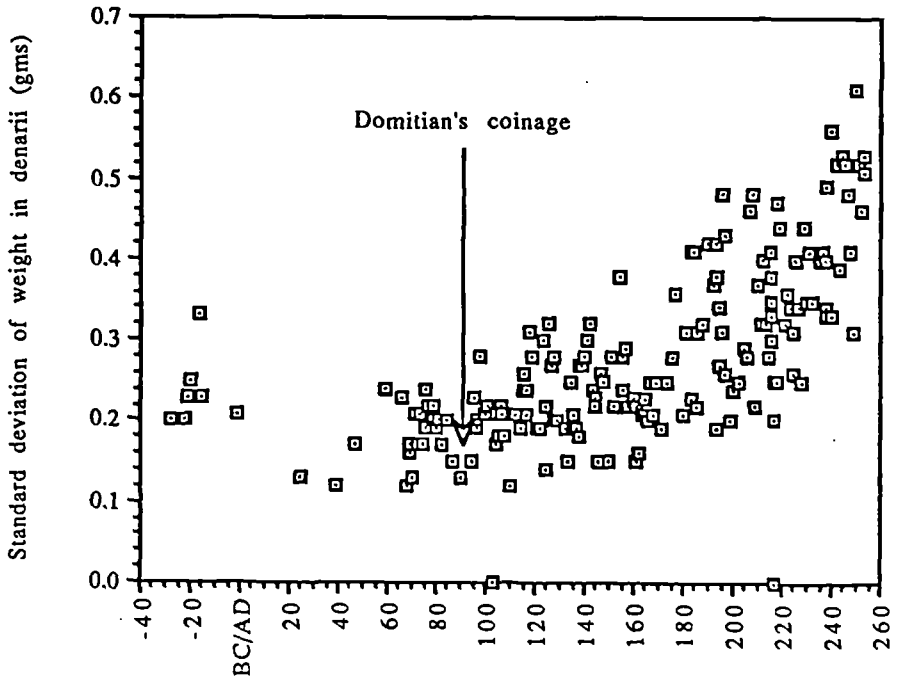

Fig. 43.09 The variability in *denarius* weight standard over time

In Upper Moesia, the lead-silver mines are thought to have been opened up by Trajan, and extended in the late Hadrianic to Antonine period. The Aeliana and Aureliana mines are probably Hadrianic, the latter name possibly relating to the young Caesar Marcus Aurelius in the last year of Hadrian's reign or possibly later. Certainly it was Marcus Aurelius who had the mines opened on Mount Kosmaj near the frontier; these were thought to be particularly profitable. This evidence suggests an early Antonine expansion of bullion going to Rome. But to judge by the associated settlements, the period of greatest prosperity around the mines came a little later under the Severi (Mócsy 1974, 133-4, 216). In Dalmatia the principle lead-silver mining area was Domavia in the Drina Valley which was certainly active in the late second century, though Wilkes (1969) provides little dating evidence.

It is difficult to draw from this any quantified conclusions about silver mining in the Roman world, however it would appear unlikely that there was a decline in the Trajanic to Antonine period. However, this is the time at which the consistency of *denarii* starts to deteriorate again. It seems that a simple equation of bullion supply against coin recycling is impossible to establish from this kind of analysis. Perhaps too complicated a picture is being forced on the data. The real answer may be that throughout the second and third century the mint simply took less care over the production of *denarii* . Whilst the source of the metal might lead to variations in the silver content of a coin, good workmanship should still result in a consistent weight. However, we find that not only does variability in the alloy content rise through the second century but so does the variability in the weight of the new coins (fig. 43.09). A gradual decline in quality control seems more likely from this evidence. In weight control as in alloy content, Domitian's coinage stands out as the exception to the rule. Here the *denarius* was being carefully monitored to a degree that no other emperor after the Julio Claudians matched. The wide variation in the weights and silver standard of the issues from the mint as the second century progressed suggest that the debasement of the *denarius* was not a precisely controlled process as Walker's interpretation would tend to suggest. The process appears to have been more like a gradual slide downwards with the occasional measured reform rather than Walker's interpretation of a precise stepped decline.

4.35 Debasement and the Velocity of Circulation

The section above has demonstrated that the circulation and wear of silver coins demands that if coin is recycled then debasement will follow if the weight standard is to be maintained. This is both theoretically demonstrated and practically demonstrated by showing the close correlation between the melt down value of the British circulation pool and the current issuing standard. It is stressed, however, that it is not known at the

moment how representative the state of wear on British *denarii* is, nor how similar the composition of the circulation pool here is to that in other provinces. However, these two questions can be addressed.

Coin wear on British coins may be similar to that on continental issues. *Denarii* were extremely mobile, so much so that it would be prudent to ask whether the weight of *denarii* in Britain is actually telling us anything about Britain per se, or is it possible that the wear on them is a far more general indicator of what is happening in the empire as a whole. Did the wear being measured actually take place in Britain, or did it take place in the whole of the Empire, with the coin simply terminating its European tour by being fossilized in a hoard in Britain ? There is no intrinsic evidence that will tell us this. Duncan Jones' analysis of the Londonthorpe, La Magura and Viuz-Faverges *denarii* hoards of Britain, Rumania and France suggested similar rates of wear in each country (Duncan Jones 1989), so this can be taken to suggest that the order of wear on the British *denarii* was similar to those in other provinces.

The second area for concern is whether the structure of British coin hoards is comparable to those from other areas of the Empire. In order to answer this a sample of 122 continental *denarius* hoards were gathered:

Italy	9
Spain	1
France & Belgium	33
Germany & Austria	24
Danube & Balkans	38
Albania & Yougoslavia	3
Syria & Palestine	2
Egypt	2
Morocco	1
W. Empire (unlocated)	9

Most of these were reported in the form of tables, and the chronological divisions did not always match those used for the British study. However, upon making the data as compatible as possible a structure analysis was run on them. The results are given in Appendix 4.33 and fig. 43.10. During two periods the scatter of points appears to be different. From about AD 70-90 the continental hoards (from a wide range of provinces) appear to be more archaic than those in Britain. This means that during this period Britain had more new currency arriving in it than many other regions of the Empire. This would fit in sensibly with the Flavian conquest of the North of Britain, whilst there was little going on elsewhere in the empire: a couple of seasons taking the Black Forest back under control, a minor war with the Parthians and later the start of trouble with Dacia. Under Trajan the picture reverses itself, five hoards show modern structures in comparison to Britain, suggesting Britain is was not getting as much new

coin as elsewhere. However, two of these come from Bulgaria shortly after the end of the Dacian Wars, so new coin could be expected here. In the Italian hoard we would also expect to find fresh coin. However, the other *two come from Egypt and Morocco.* We can only conclude in the negative that the circulation medium in Britain need not have been radically different from that in Gaul or Germany, we simply have no evidence. It was different to areas of current military activity, and the heart of the empire, and it was also different to North Africa. These differences must not be over stated, they all lie within the range of variation in the British hoards (see. Fig. 25.10-11), and in general the plotted hoards lie close to the line. Since all the continental hoards lie within the variation of the British data it can be assumed that the British 'normal hoard' structure is not a bad surrogate for an Empire-wide picture, pending further research.

The model also relies on the assumption that coins were not selectively called in. However, we know this was probably the case when the Republican coins disappeared, possibly under Trajan (Sperber 1974, 135-6). However, despite these problems, coin wear can be shown to be a major contributory factor to the debasement of the *denarius*, and I believe it to be the principle factor.

Debasement cannot now simply be interpreted as the act of Emperors short of money making the mint produce more, or at least not in the case of the *denarius.* Even without recycling and reminting, coin wear reduced the average silver content of the *denarii* in circulation. This requires the creation of alternative economic interpretations for what was happening. Previously debasement and inflation were linked, now debasement can also be linked to the velocity of circulation of *denarii* .

If this wear/debasement model is correct, we would expect the greatest sign of debasement to be taking place when money circulated most rapidly. Conversely, we would expect stability in the silver content of *denarii* when coin was not being worn, when it was moving around slowly. Examining Walker's simplified picture of the process (Figs 43.11) there are two principle periods of debasement. The first was under Nero and the civil war that followed, thereafter there was a period of virtual stability (apart from Domitian's brief attention to the coin). The second phase starts with the debasement of Antoninus Pius in AD 148 which began a new decline which this time proved to be terminal. These two periods, the mid first century and the mid second century onwards, were also the times when coin wear on *denarii* in Britain and elsewhere was at its height. The lull in the debasement of the *denarius* also correlates with the period of minimal wear (section 2.3). Debasement therefore seems to be a symptom of the degree of circulation of coinage.

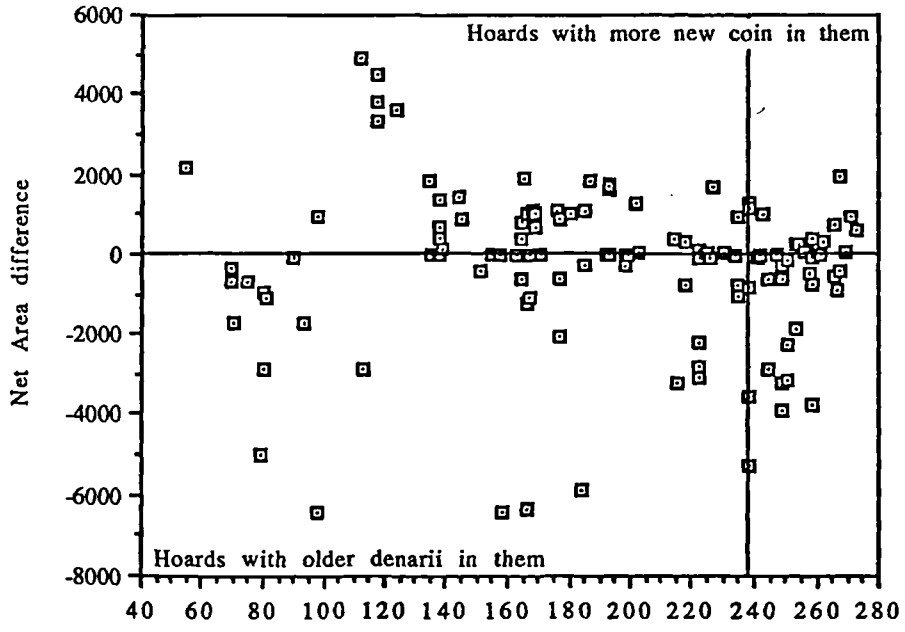

Fig. 43.10 The structure of continental *denarius* hoards against the British benchmark.

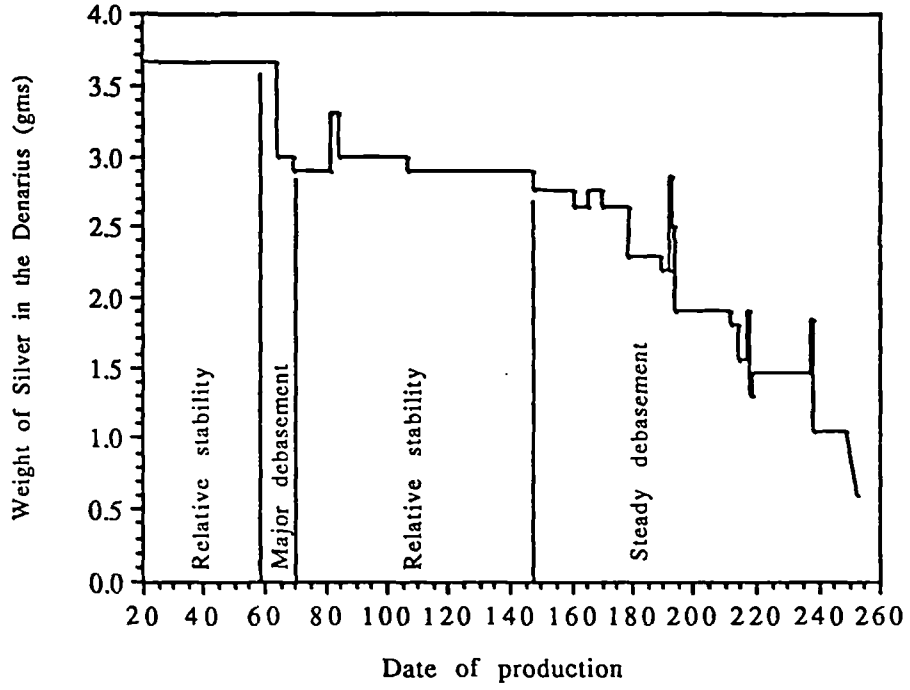

Fig. 43.11 Walker's simplified chronology of the debasement of *denarii*

The profit motive at the mint in Rome was not the prime causal factor behind the decline and fall of the Roman *denarius* . The later second century emperors may have made a slight profit (the curves in fig. 43.07 do diverge marginally here), but at the same time we must also note the severe decline in quality control at the mint. In general the silver content of the *denarii* of the day followed closely the path of the average melt down value of the coins in circulation. The faster the *denarii* circulated the more they got worn and the faster the silver content of the *denarius* fell. The coin was too successful for its own good.

4.4 The *denarius* to *antoninianus* transition

In 215 Caracalla introduced a new silver coin which we know as the 'antoninianus'. Whilst it did not immediately replace the denarius (indeed it was not produced between 222 and 238) by 244 the denarius had ceased to be issued as a regular part of the currency. This section examines some of the associated events. First the evidence of denarius imitations is assessed (4.41), then the pattern of hoards and site finds is examined to see what light they throw upon the subject (4.42).

4.41 The imitation of *denarii*

In the late second century and early third a large number of base *denarii* arrived in Britain minted by the Severans. A large influx of coins would have had one of two effects, either it would have lead to an increase in prices or else it would have resulted in a drop in the circulation rate of *denarii* (See section 4.51). However there is no evidence for a rapid rise in prices at this date in the Roman World in general (though it must be admitted there are hardly any prices for anything from Britain). The main price rises noted are those from AD 260 onwards, much later in date. The alternative was that there was for some reason price stability (social pressure ?) and that instead of the prices rising, the velocity of circulation of *denarii* fell substantially. In fact this is precisely what our study of hoard structure suggested. In 215 the '*antoninianus*' was introduced tarrifed at either one and a half or two *denarii*, the subject is a matter of some dispute: as will be shown it only arrived in Britain in substantial numbers rather late in the day, but the requirements for its production meant that *denarii* were called in to be melted down. Our money supply curve suggested that there was a fairly sudden decline in the number of *denarii* in circulation around 230-40, the same date as the re-introduction of the *antoninianus* after a brief period of its suspension from production (c.16 years). Such a chronological correlation is not unlikely but further evidence can be found to support it. First, if the number of *denarii* in circulation fell rapidly and they were not replaced by similar numbers of new *antoniniani* then a shortage of coin might result in copying. This is indeed found.

'Forged' *denarii* and other coins of the late second and early third century are not uncommon on British sites, nor are the moulds from which they were produced. One of the largest recent finds of moulds came in 1988 from Blomfield (London) where hundreds of fragments were found in the ditch of the Roman defences. Further moulds have been found in quantity elsewhere: Edington (Somerset); Lincoln, Ancaster and Bottesford (Lincolnshire); Lingwell Gate (near Wakefield, Yorkshire); and Ryton and Wroxeter (Salop) (Sutherland 1937, 43); and many other sites have produced moulds,

though in smaller numbers. The context in which they need to be viewed is the end of the *denarius* as the principle silver coin in Britain. The '*antoninianus*' which replaced it was first introduced in 214 by Caracalla, although production was discontinued under Elagabalus. Balbinus and Pupienus revived the issue in 238, and from Gordian III production of the *denarius* became very uncommon. This point marked the end of production of *denarii* to all intents and purposes, though occasional small issues were produced. Sutherland pointed out that many of these smaller sites had casts of Severan coins, but not later types: "Consequentially it is reasonable to fix the active and general beginning of mould-made *denarii* within the reigns of Severus and Caracalla." (1937, 46). This he saw continuing in some areas as late as Alexander. He concluded:

> "...it is best to conclude of the British moulds that they represent an attempt, certainly illicit, though perhaps not made without semi-official connivance, to bolster up the strength of the *denarius* in face of competition by the antoninianus. When the latter denomination was supreme, the series of moulds peters out. This explanation frees us from the difficulty of explaining why casting was not busily practised from circa AD 240-60, when silver dropped to a record low-frequency point; although silver was so scarce, it was useless to continue the fight to preserve the *denarius* after the *denarius* had virtually suffered official abandonment."
>
> (Sutherland 1937, 47-8)

The most recent updated survey of these has been by George Boon (1988, 124-6). Most of the moulds and coins are Severan, though some earlier ones are found whilst others continue to Severus Alexander and Maximinus. Despite the Severan date for the majority of them (AD 193-211), Boon differs in his interpretation of their date from Sutherland, dating the majority of them later to the re-introduction of the *antoninianus* in 238. The cause being related to the denarius' premium silver content against the over-valued *antoninianus* . The Blomfield (London) find, copying *denarii* down to Maximinus (235-238) helped to confirm this, however later bronze coins were also copied in the hoard down to Gallus (251-253).

A further way of examining the problem would be to look at the assemblage of imitation *denarii* as a whole rather than as a chronological series of individual emperors. Then it would be possible to see at what date this mixed assemblage most closely corresponds to the general circulation pool which it was meant to imitate. The comparison is made in fig. 44.01 (based on a corpus of 90 site finds of such coins: Appendix 4.41; these are drawn from the site-find database outlined in section 3.2). The ratio of copied types compares most favourably with the composition of the circulation pool between AD 230 and 240. This seems to confirm Boon's argument for a later date of manufacture and removes any necessity of envisaging any of the copies being made as early as the reign of Septimius Severus, despite his coins being the most

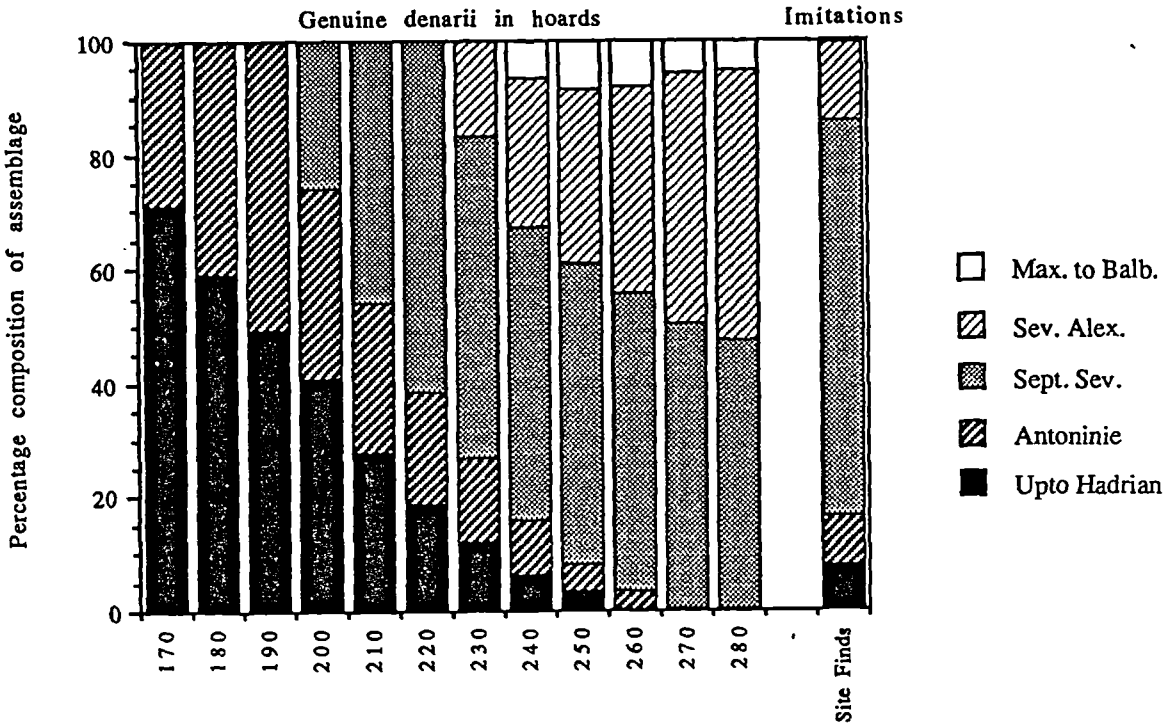

Fig. 4.4.01 Silver plated *denarius* copies and the circulation pool

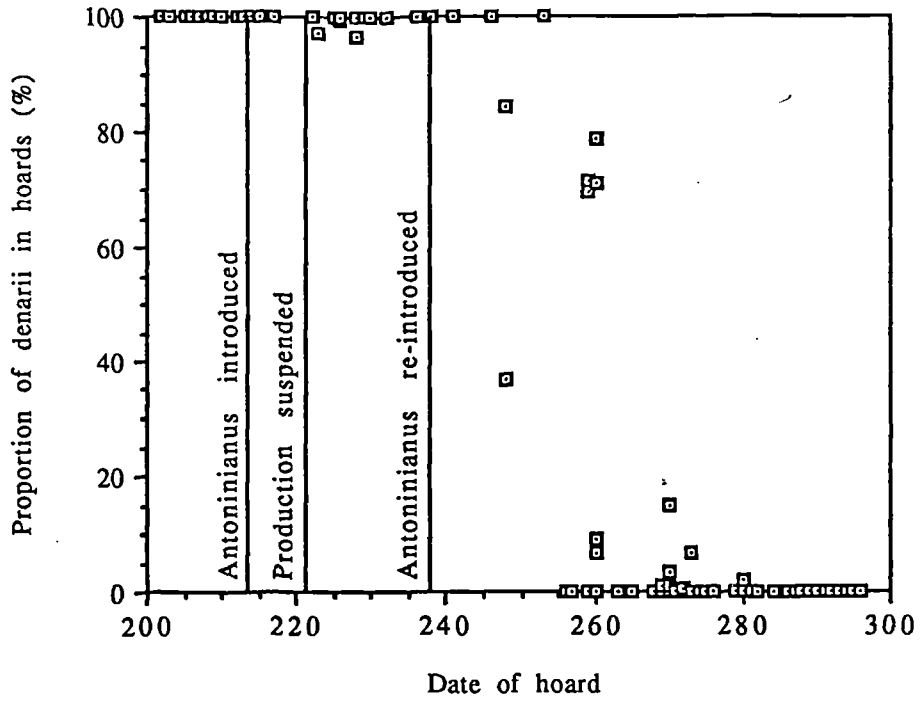

Fig. 44.02 The proportion of *denarii* to '*antoniniani*' in hoards

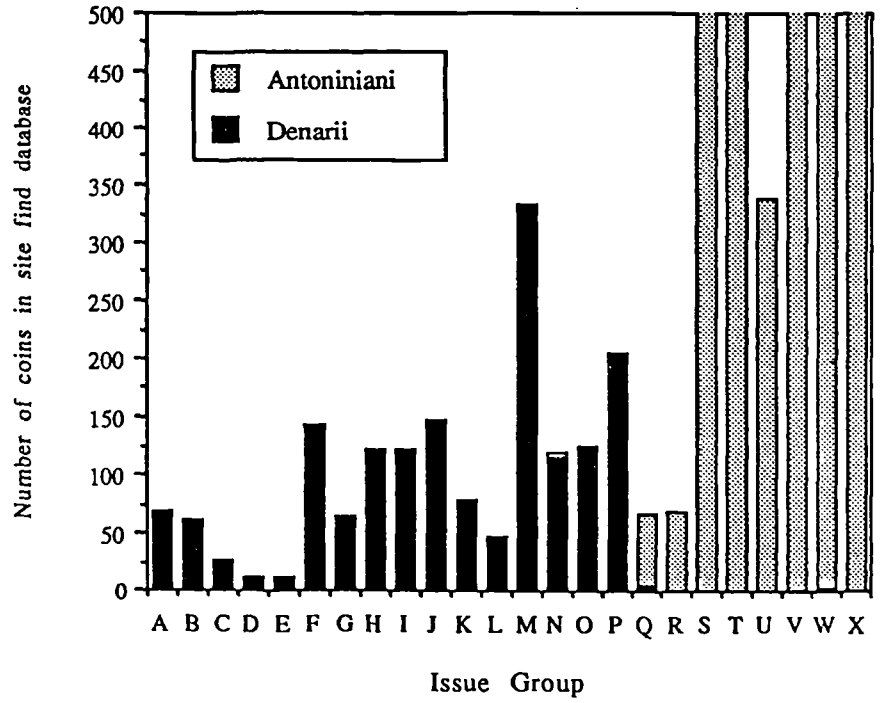

Fig. 44.03 The number of *denarii* and '*antoniniani*' as site finds

frequently copied. The worn condition of many of the coins used to make the moulds also supports this view.

If all these copies were made around AD 238 and thereafter, it is interesting that the *denarii* copied are a match for all those coins in circulation at that date, rather than being biased towards the imitation of the earlier silver rich *denarii*. If earlier *denarii* had circulated at a preferential rate, then surely they would have been preferentially copied. But this appears not to have been the case (cf. Section 4.8).

4.42 The hoard and site find evidence

A second method to look at the transition between the *denarius* and '*antoninianus*' is to examine their joint hoarding pattern. Fig. 44.02 shows the proportion of *denarii* in 'silver' hoards. As will be seen, whilst the *antoninianus* nominally takes over from the *denarius* in 238, the practical reality in British hoards would date this switch about 15 years later, in the late 250s.

There are very few hoards that can be dated to the 240s or early 250s. Those which do can still contain a very high proportion of old *denarii*. It might be the case that some of the earlier *denarius* hoards ending with coins of the 230s were in fact deposited later, but owing to the absence of any *antoniniani* in them we cannot tell this. In general the lack of '*antoniniani*' in hoards for a couple of decades either suggests that people suddenly stopped hoarding, which is unlikely, or else it simply reflects that there were relatively few of the new coins around.

A glance at the number of site find *denarii* and '*antoniniani*' (Fig. 44.03) shows that in both periods Q (Balbinus to Hostilian) and R (Trebonianus Gallus to Valerian) some *antoniniani* reached the province. However first the level is lower than the supply of *denarii* in the late 2nd century and early third, also in the late second and early third century the arrival of *denarii* was topping up an existing circulation pool, where as here the first supply from Balbinus to Hostilian represents virtually the entire stock of the new coin in the country. This all suggests that until Gallienus there was a shortage of *antoniniani* in Britain.

4.43 Conclusion

Denarii were copied on a large scale. The coins copied generally reflect those in circulation upon the date of the reintroduction of the *antoninianus* and probably reflect the rapid disappearance of *denarii* in circulation. This shortage lasted for a significant period with the occasional copying continued as is evident from the Bloomfield find.

Stability only came with the arrival of *antoniniani* of Gallienus. But what effect did this dearth of coinage have upon the market? This is explored in the next section.

4.5 The quantity theory of money and cyclical trends in the economy

The quantity theory of money is introduced, relating the variables of money supply (M), velocity of circulation (V), prices (P) and the quantity of goods and services being transacted within the monetary economy (Y) (4.51). In the following sections three of these variables are established (4.52-54) leaving only Y unknown. The three variables are inserted into the equation to generate a picture of Y (4.55). The peaks and troughs in this curve are then related to archaeological evidence from Britain (4.56), and then the picture is related to broader changes in the economy of the Empire (4.57-8).

4.51 The quantity theory of money

The quantity theory of money is an old idea allegedly dating back to Confucius (Begg et al 1984, 611), but its first systematic formulation came in the first half of the 18th century with the economists David Hume, Richard Cantillon and Joseph Harris. Its best known formulation is that devised by the American Irving Fisher (1867-1947), indeed the equation is frequently known by his name:

$$MV = PY$$

Where M represents the money supply
P represents the price level
Y represents the quantity of goods and services being exchanged for money
V represents the velocity of circulation (the number of times money is circulated to service the exchanges yielding the nominal income, PY).

These expressions are identities; they are always true by definition.

Monetarist explanations of the economy explained inflation in terms of too much money chasing too few goods: i.e. if there was an increase in the quantity of money (M), and the number of goods (Y) in the economy did not change then prices (P) have to rise. Indeed Milton Friedmen (1968) asserted that 'inflation is always and everywhere a monetary phenomenon'. One of the problems here was that these statements failed to take into account the possibility of changes in the velocity of circulation of money. So that in the late 1980s this brand of monetarism got a very bad name. The trouble is that in present day economies V (the velocity of circulation) is very difficult to measure, so it is often assumed to remain constant:

> "One justification for assuming [that V remains unchanged] is the belief that methods of using money in exchange are stable. But it is important to recognise factors which may induce changes in the velocity of circulation. ... once an economy is monetised, transactors seek more convenient and less costly ways of conducting exchange. For example, the advantage was shown of token money over gold, and that of bank money over token money, at least for some transactions. Now, as transactors use new ways of transacting, so they change the velocity of circulation. Perhaps the most important recent example of changes in the payment mechanism is the use of credit cards. The general acceptability of payments by credit card reduces the number of times money is circulated to service that sequence of exchanges which yields nominal income. The assumption of stability is acceptable if few such institutional changes take place over the period under consideration."
>
> (Creedy et al., 1984, 352)

There have been discussions of Fisher's equation in relation to the ancient world before now, but usually only two variables have been examined: prices and quantity.

> "Can Fisher's equation be applied to the ancient Roman world? Of course there are immediately all sorts of problems, mostly stemming from the lack of information ... about the quantity of goods in circulation within the Roman Empire, and more importantly, whether it varied significantly from period to period. Little is known about alterations in the velocity of the exchange of money. Thus I shall assume rashly, but in common with most discussions of the subject, that v(elocity) and q(uantity of goods) remained broadly constant, and concentrate on the remaining elements, m(oney) and p(rices)."
>
> (Burnett 1987, 105-6)

But solutions to these problems do exist. Modern economists may find difficulty measuring the velocity of circulation of money, but for Roman Britain two methods have *already* been used (sections 2.3 and 2.5). *Denarius* and *sestertius* supply figures have also been established (sections 3.5 and 4.2) which brings us some way towards two of the elements in Fisher's equation. If we could establish an index figure for the changes of price levels in Britain - or at least for the Empire as a whole then it might be possible to generate a curve reflecting the number of goods in the cash economy in Roman Britain. Such a curve could then be tested against the archaeological evidence. But first we need to establish the three variables for the equation: M, P and V.

4.52 (M) An index of the money supply

In sections 3.5 and 4.2 an attempt was made to estimate the changing pattern of the number of *denarii* and *sestertii* in circulation in Britain. However, the changes noted were only relative since the vertical axes had no definite scale. *Denarii* and *sestertii* were however only two of the forms of money in Roman Britain, so before using either or a combination of them in Fisher's equation it would be prudent to examine precisely what the term 'money-supply' means in this context.

Money supply has a variety of definitions. In its most basic form it is the amount of cash circulating in the economy, however the existence of even the most basic financial instruments and devices can complicate this. This has led to a proliferation of definitions of money supply to cope with the modern world. In the present day 'money' exists in a variety of forms from its most liquid form, cash, to more inaccessible deposits in interest-bearing accounts. These different types of money are added together to create a hierarchy of definitions from M1 (cash and current accounts only) to M3 (which includes public and private sector deposit accounts as well as deposits held in currencies other than sterling). These additional sources of money added into the equations are sometimes called 'near money' because though investment deposits in banks and foreign currency are not in themselves means of payment, they can readily be converted into such.

If we turn to Roman Britain the most basic definition of money would be the cash in circulation and in hoards (the equivalent of directly accessible current accounts). However, to what extent were there other forms of money around? We know that a form of letters of credit existed in the world of Mediterranean shipping, and Cicero used similar letters of credit from his banker Atticus to help finance his governorship in Cilicia. So it is quite probable that similar financial instruments were used in cross channel trade with Britain; but how would that have effected the money-supply for the province as a whole?

Banking institutions are also important to guard against. If any form of banking can be demonstrated where money is held and letters of credit pass in lieu of cash, then this opens up the possibility of the banker making loans from the bank's reserves thus increasing the stock of *money* in the economy without any increase in the quantity of *hard cash* in the system. This is how:

If a banker simply looks after other people's money with it being occasionally deposited and withdrawn, this would have no effect on the money-supply. However, things might develop so that letters of credit came into existence. These are documents which could pass instead of cash transferring the ownership of deposits in the bank, without cash actually having to be drawn out and redeposited again (eg. cheques). This on its own would have no direct effect on the money supply since the letters of credit equal the cash deposits frozen in the bank; so the money supply would still be equal to the total amount of cash in circulation and in the bank. However, if the banker lent out some of the cash reserves this *would* lead to an increase in the money supply. This is because the quantity of money in circulation has increased because of the money out on loan, but people's perceived deposits in the bank have not decreased, despite the fact that the

cash is not in fact there (Iucundus at Pompeii is an example of this in operation in the Ancient world - Andreau 1974). So if in Roman Britain there were both letters of credit and bankers lending people other peoples money then this would confuse the simple equation of the coin supply figures with the money supply figures.

The most extensive banking system at the time was probably that of the Roman Army. Whilst legionaries may have had a nominal income of 225 *denarii* after Caesar much of this was withheld in payment for clothes and other expenses and the rest held on account. One of the most revealing documents of this kind of practise comes from the details of the account of Iulius Proculus from Damascus c. AD 81 (*Pap. Lat.* I). The account records the three annual payments, here of 248 *drachmas* each (62 *denarii*). From this various deductions are made and the balance goes into his savings account:

Received	1st payment 248 dr	2nd payment 248 dr	3rd payment 248 dr
- bedding ?	10	10	10
- rations	80	80	80
- boots	12	12	12
- annual feast	20	-	-
- burial club	-	4	-
- clothes	60	-	146
EXPENSES	182	106	248
Remainder deposited to his account	66	142	0
Balance carried forward	136	202	344
New Balance	202	344	344

It is important to note a number of things, especially the fact that these figures do not show any withdrawals of cash from the account. Part of the reason may be that the 248 *drachmas* or 62 *denarii* did not represent the legionary's entire pay. A third of 225 *denarii* should have been 75 *denarii* , so the shortfall of three payments of 13 *denarii* may have been handed over in cash and known as the *acceptum.* (Watson (1969, 221) and Webster (1985, 267)). But this is hardly an interactive current account, and may be more of a way of the state indefinitely deferring a proportion of its recurrent annual expenditure.

So some kind of banking system existed within the army, but we have not demonstrated this in Britain yet, nor shown the existence of 'letters of credit' or for banks making loans. However, evidence for two of these comes from one of the Vindolanda writing tablets. This is the letter from Octavius to Candidus, probably dating to the early second century (Bowman et al.1990). The letter will be discussed further in the conclusion so it will be repeated here in full:

> "Octavius to his brother Candidus, greetings. The 100 pounds of sinew from Marinus - I will settle up. From the time when you wrote me about this matter, he has not even mentioned it to me. I have several times written to

> you that I have brought about 5,000 modii of ears of grain, on account of which I need cash. Unless you send me some cash, at least 500 *denarii* , the result will be that I shall lose what I have laid out as a deposit, c. 300 *denarii*, and I shall be embarrassed. So, I ask you send some cash as soon as possible. The hides which you write are at Cataractonium - write that they be given to me and the waggon about which you write. And write to me what is with that waggon. I would have already collected them except that I did not care to injure the animals while the roads are bad. See with Tertius about the 8 1/2 *denarii* which he received from Fatalis. He has not credited them to my account. Know that I have completed the 170 hides and I have 111 (?) modii of threshed bracis. Make sure that you send me some cash so that I may have ears of grain on the threshing floor. Moreover, I have already finished threshing all that I have. A messmate of our friend Frontius has been here. He was wanting me to allocate (?) him hides and that being so, was ready to give cash. I told him that I would give him the hides by the Kalends of March. He decided that he would come on the Ides of January. He did not turn up, nor take any trouble to obtain them since he had hides. If he had given the cash, I would have given him them. I hear that Frontinius Julius has for sale at a high price the leather ware (?) which he brought here for 5 *denarii* apiece. Greet Spectatus and ... and Firmus. I have received letters from Gleuco. Farewell."
>
> (Bowman et al.1990)

Octavius's activities must have been related to army supply, especially considering the quantities of material he is discussing. 5,000 *modii* of wheat would have fed from 67 to 167 people for a year. 67 people using Davies' (1971, 123) consumption figure of 3 lb of grain a day, or 167 people based on the subsistence level of the grain dole in Rome of 30 *modii* per annum (Garnsey 1983, 118). If we are looking for evidence for 'letters of credit', or rather transfers of money taking place without cash having to physically move distances, then the sentence "See with Tertius about the 8 1/2 *denarii* which he received from Fatalis. He has not credited them to my account" suggests that this was certainly possible. However, this is, more probably than not, a transaction within the closed community of the army. All the transactions with other people appear to be in cash. Octavius asks for cash to pay for the rest of the grain, again in relation to an order for hides and threshed bracis, and the transaction with the elusive friend of Frontius would have been acceptable had it been in cash. No mention in these cases is made of accounts, despite the large scale of expenditure. So despite the presence of some form of credit system with the military community this letter provides no evidence for its extension to military suppliers such as for the grain. Whilst one document represents very little to go on it seems safest to assume that whilst the Roman Army in Britain did run some form of banking system with transfers between individuals being possible, this was probably a limited closed system within the confines of the army.

The next question is did the army treasury make loans to people? A Hadrianic ostracon from Egypt suggests that they could give advances to soldiers of army pay (Lewis & Reinhold 1955), however this does not count as a loan which would increase the money supply. In effect the army was lending the man his own money since he would have

partaken in the compulsory savings scheme. In summary the banking system within the Roman Army in Britain is unlikely to have made much impact on the money-supply of Roman Britain in terms of extensive loans or army pay advances.

The other evidence for loans in Britain we have is of those from Seneca and others to leading Britons which were called in shortly before the Boudican revolt. If Seneca was lending his own money then this would not add to the money-supply figures for the Empire, since it needs to be someone else's money being lent while they are still able to use it via letters of credit. If the loans arrived in the province in the form of hard currency then they will have been included in the *denarius* and *sestertius* supply calculations.

Evidence for other forms of banking do not come from Britain, but appear in Roman law codes. It appears that interest bearing deposit banking did develop (*depositum*) probably by the Antonine period (Garnsey & Saller 1987, 55; Digest 16.3.28,24,26.11). However, again, even though the banker probably lent out the money to pay interest, money supply figures would only be enhanced by the account holder being able to utilise the money at the same time in the form of letters of credit from the bank, and the evidence for this is still minimal.

It seems safe to suggest that the money supply figures for Roman Britain would probably equate well with the supply of coinage. However, we only have supply curves for two of the denominations: *sestertii* and *denarii* (figs. 42.07 & 35.02). Since the *denarius* was the principal medium for the storage of wealth in the country, to judge from hoards, then it is probable that its curve is going to represent the bulk of the money tied up in coinage in Britain in terms of value. The trends in both curves are not dissimilar. The *denarius* curve has a Claudian peak, which as stated should probably have lasted slightly longer, whilst the *sestertius* curve also had an early peak through from Nero into the early Flavian period. Both curves hit a low point in the late first century, and both subsequently rose up until the Antonine period whence they diverge as the shipment of bronze to Britain effectively ends and the number of *sestertii* in Britain slowly declines.

For the purposes of this exercise the *denarius* supply curve will be taken as a surrogate for the sum value of all the denominations in Britain. Since other denominations are excluded, only the broadest trends from the results from Fisher's equation can be taken as potential reliable.

4.53 (P) An Index of Prices

The next variable we need is an index of inflation for Britain. Unfortunately there is very little data available to do this for the Empire, let alone an individual province. In looking at the empire as a whole one must guard against the possibility of regional price differentials. In Egypt and Sicily wheat may have been much cheaper than in less fertile areas. Nonetheless it has been thought worthwhile to attempt to reconstruct an index of inflation for the Empire as a whole, to see if such a thing is possible, or else to see if regional variations make such a task futile, which in itself would be informative.

The most commonly stated price is that of wheat. Four principle collections of wheat prices have been gathered (Appendix 4.51):

VARIOUS AREAS	J.P. Callu, La Politique Monétaire des Empereurs Romains de 238 à 311, Paris, 1969, pp 395-396.
PALESTINE	D. Sperber, Roman Palestine 200-400, Money and Prices. Ramat Gan, 1974, p 124 & 247. After West & Johnson, Currency, p 81 and Johnson in JJP, 4, 1950, p 156.
LOWER EGYPT: Official	R. Duncan-Jones (1990), Structure & Scale in the Roman Economy.
LOWER EGYPT: Private	R. Duncan-Jones (1990), Structure & Scale in the Roman Economy.

All these prices cannot just be used together. For example the Egyptian official price for wheat was lower than the market price, but nonetheless both experienced fluctuations. Similarly because Palestine may not have been quite so fertile other factors may have played on prices there. Each price series needs to be converted to a standard. Each series of values has been plotted separately, and the interpolated price of wheat at about AD 150 had been given the indexed value 100. All other prices have been altered correspondingly. As an example the official price of wheat in Lower Egypt around AD 150 was c. 8 *drachmas* per *artaba* . So 8 *dr.* is given the value of 100 units. Hence in AD 246 when the price was 24 *drachmas* the index would be 300 units. This means that all the four price series can be plotted on the same scale without regional variation entering the data set (with the exception of Callu's figures).

All the converted wheat prices are shown in fig. 45.01. The most notable feature is the massive price inflation after 260. Fig. 45.02 shows the earlier section in more detail. Generally prices can be seen to rise from the earliest period to the early third century, however it is questionable whether prices necessarily rose consistently during this period. From the late first century to the mid second century one could possibly see a fall in the price of wheat. This can be seen in the scatter of prices and the fitted polynomial, though it must be emphasised that the quality of the data is not sufficient to state categorically that prices actually fell in this period, but it should make us aware of this possibility. Since three of the sources are prices from the Eastern Mediterranean, how relevant to the Empire as a whole is this? The answer lies in looking at the values

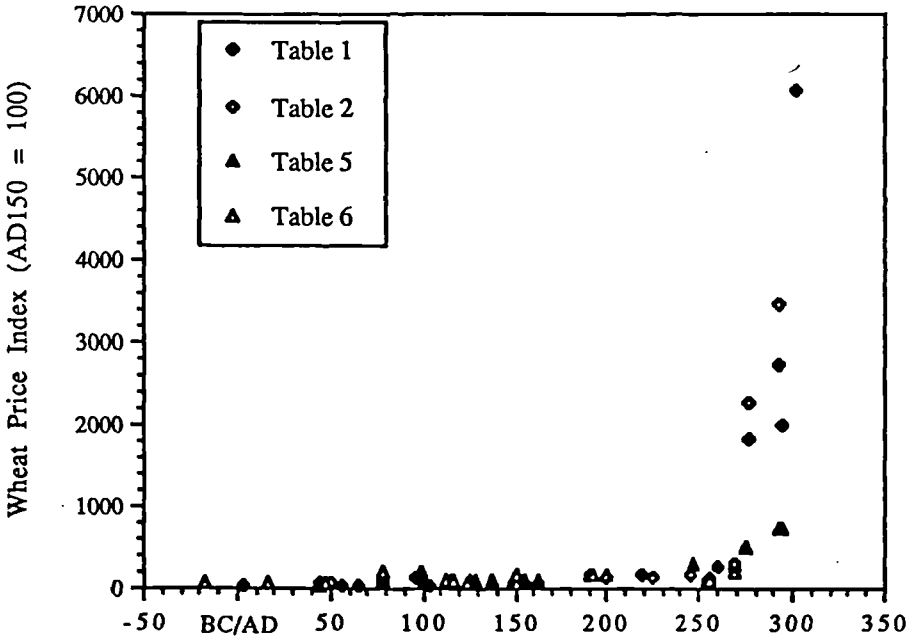

Fig. 45.01 Wheat Prices: 50 BC to AD 300

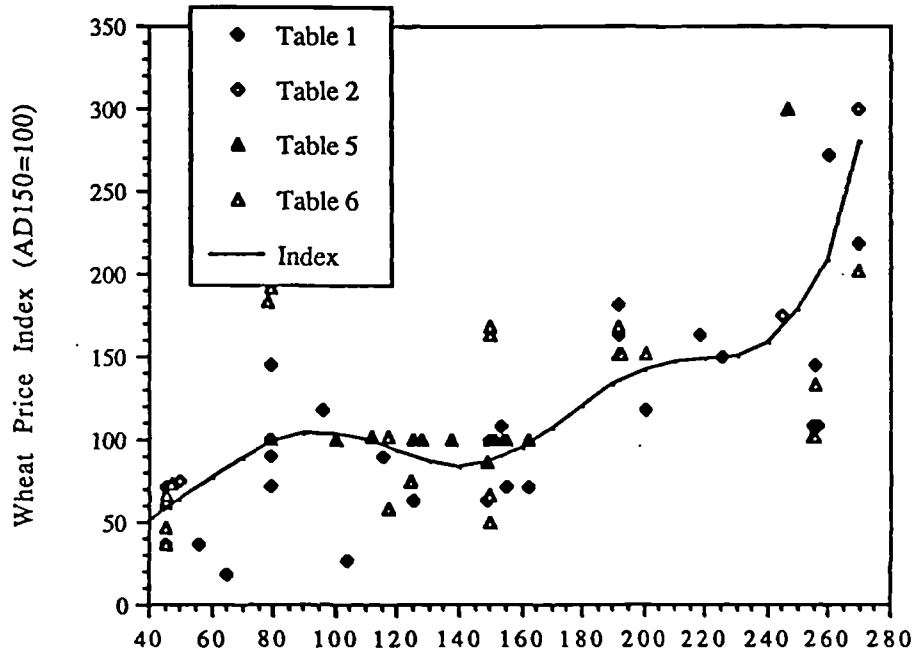

Fig. 45.02 Wheat Prices: AD 40 to 280

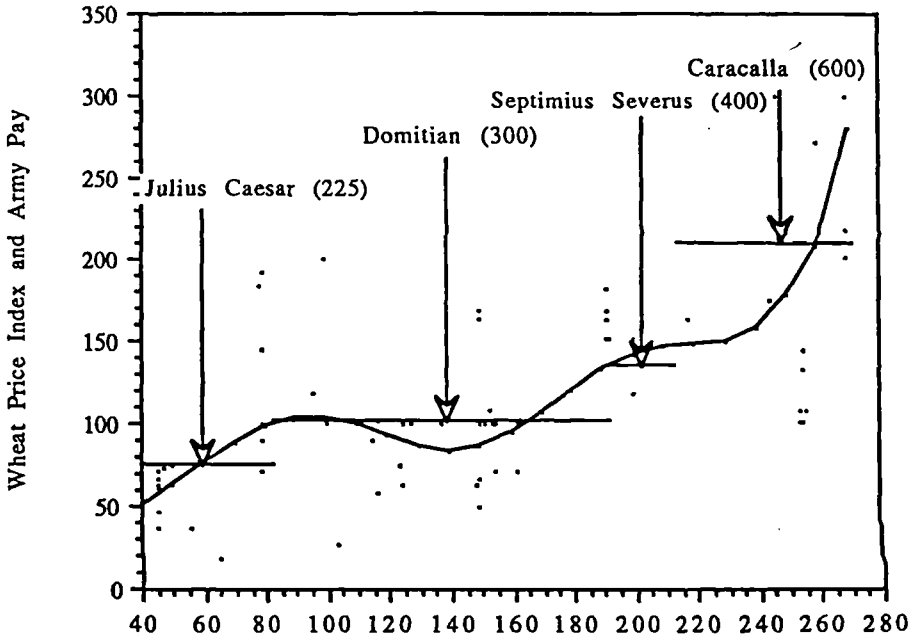

Fig. 45.03 Wheat Price Index and Army Pay

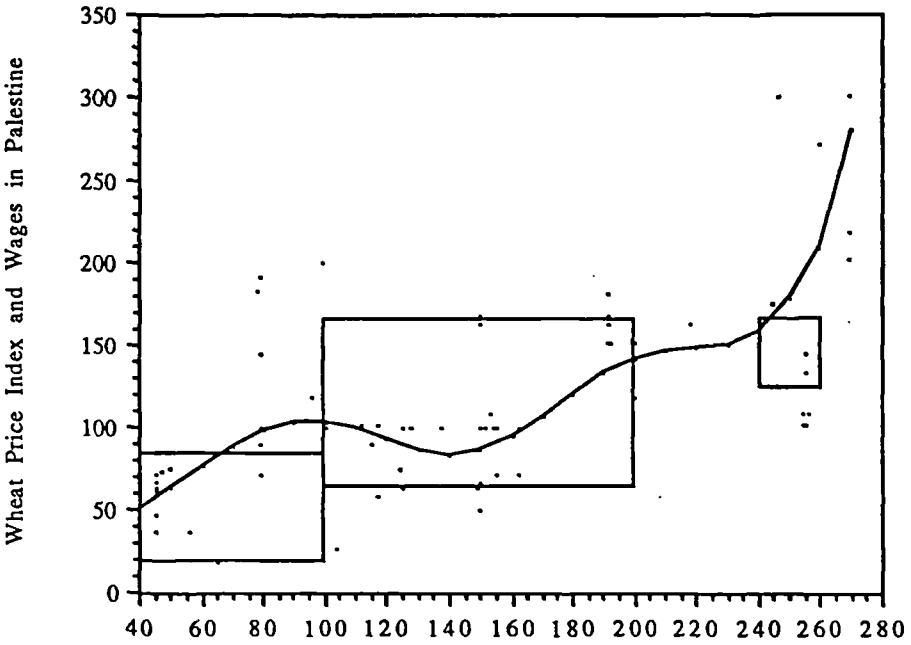

Fig. 45.04 Wheat Price Index and Wages in Palestine

from Callu's corpus hence its inclusion despite the geographical variation in its sources (Table 1). These prices lie on either side of the index and do not have a markedly different distribution to the others. So this index can be taken as a crude, but for our purposes useful, indicator as to changes in the price of wheat.

We do have one wheat price from Britain. This can be derived from the letter from Octavius found at Vindolanda (above). In it he states he has already put down a deposit of about 300 *denarii* on 5,000 *modii* of wheat, and that he needs at least another 500 *denarii* soon to pay for it otherwise he will loose the deal. This gives us a minimum price for wheat of 2.56 HS per *modius*, during the early second century. Comparable prices were as follows:

Antioch	2 1/4 HS per *modius*	Late 1st c. AD	(Duncan Jones 1990, 150)
Africa	2 1/2 HS per *modius*	Late 2nd c. AD	(Duncan Jones 1990, 150)
Italy	4 HS per *modius*	Early 2nd c. AD	(Duncan Jones 1990, 150)
Egypt	2 1/2 HS per *modius*	AD 98-192	(Duncan Jones 1982, 365)
Britain	c 2 1/2 HS per *modius*	Early 2nd c. AD	(Octavius' letter)

This suggests that the wheat price in Britain was not radically different from those in the Empire as a whole (the only deviant city in the Empire was Rome itself with a price almost double that elsewhere). However, this is only on the basis of one value from Britain, and wheat is only one commodity, wage inflation and commodity inflation may have taken place at different rates. It is possible to test the index against two salary scales. The first is the pay levels of the Roman legionaries, the second are wages in Palestine (Appendix 4.81). Both have been indexed using the same method and have been plotted on top of the background of the wheat price index (figs. 45.03 & 45.04). In both cases there seems to be a general correlation between the wheat price index and nominal labour costs ('nominal' since as has been pointed out Roman legionaries probably never got their entire pay entitlement at the time).

In conclusion the general agreement between the wheat price series and the labour cost values suggests that the wheat price index is a useful device that can with due caution be taken to represent the level of prices in the Empire as a whole.

4.54 (V) An index of the velocity of circulation

Two methods were used for calculating the velocity of circulation of *denarii* . One was based on coin wear and the other analysing the variation in *denarius* hoard structures (2 versions). Both methods showed a reasonable degree of correlation. However, the use of hoard structure results are more appropriate for this analysis. The problems with the coin wear results are as follows: first the method was based on coins from a sample of 15 hoards rather than the 145 from the hoard structure analysis. Secondly the

chronological span of the hoards with published coin weights did not last as long as that for the structure analysis. Thirdly the variation in the rate of wear curve was restricted to showing a simple curve by the nature of the polynomials fitted.

The two methods were based on the calculation of the 'net area difference' and the 'best fit date' of each hoard. The first compared a hoard against the structure of contemporary hoards and measured the difference. The second scanned the period from AD 40 to 280 until it came to the date where the sample hoard was most similar to the average hoard. The difference between this date and the hoard's TPQ was then calculated. These two techniques gave very similar results (cf. figs 25.12 & 25.15):

Conquest to AD 80:	A growth in the variability of hoards (velocity of circulation falls)
AD 80 to AD 120:	A sustained high variability in hoards (velocity of circulation low)
AD 120 to AD 200	A decline in the variability of hoards (velocity of circulation rises)
AD 200 to AD 220:	A growth in the variability of hoards (velocity of circulation falls)
AD 220 onwards:	A decline in the variability of hoards (evening out as production ceases)

The resolution of the data can be marginally refined by combining the two data sets. Both readings can be plotted against each other, providing a straight line and thereby an equation by which the results of one method can be converted into the other (fig. 45.05). Once converted to the same scale (Appendix 2.55) they can be plotted as before (figs. 45.06-45.08). It is this combined curve that will be taken as an index of the velocity of circulation of *denarii* in Britain. Since the *denarius* represented the major portion of the cash supply to the province, its circulation will be taken as a surrogate for the circulation of all the other denominations as well.

One problem remains. Whilst the changing diversity of hoards may be equated with the rate of circulation of coinage the two variables are inversely related: when the velocity of circulation is high, the diversity in hoards is small, so this variable needs to be turned on its head. Since this is only an approximate calculation looking only for the broadest changes we could suggest that there is a direct inverse relationship between the variation in hoards (H) and the velocity of circulation (V). Hence $V \alpha 1/H$. So if $Y = MV/P$, then $Y \alpha M/PH$.

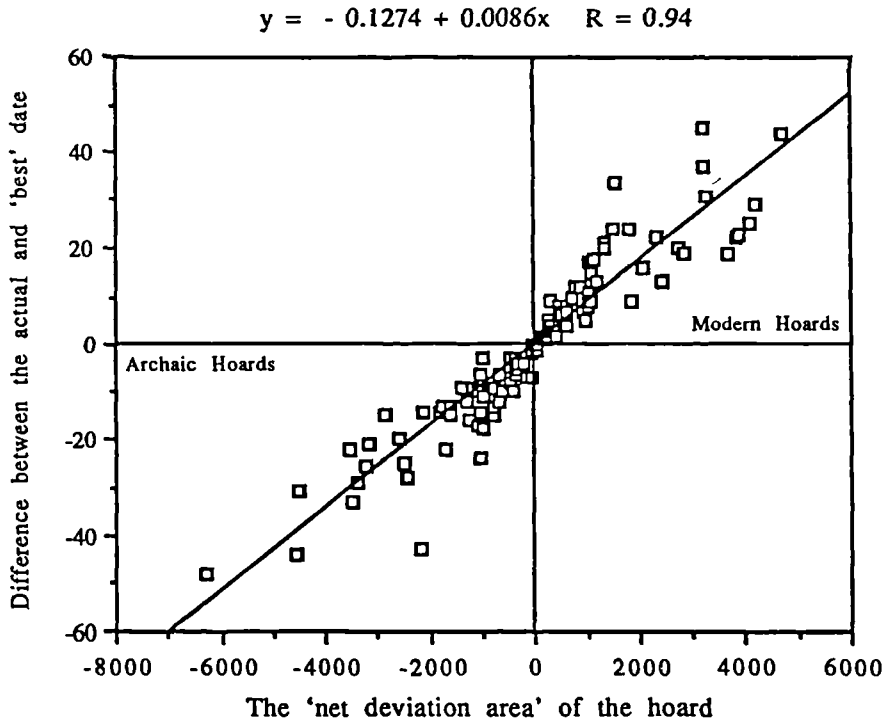

Fig. 45.05: The correlation of the two hoard structure analysis measurements

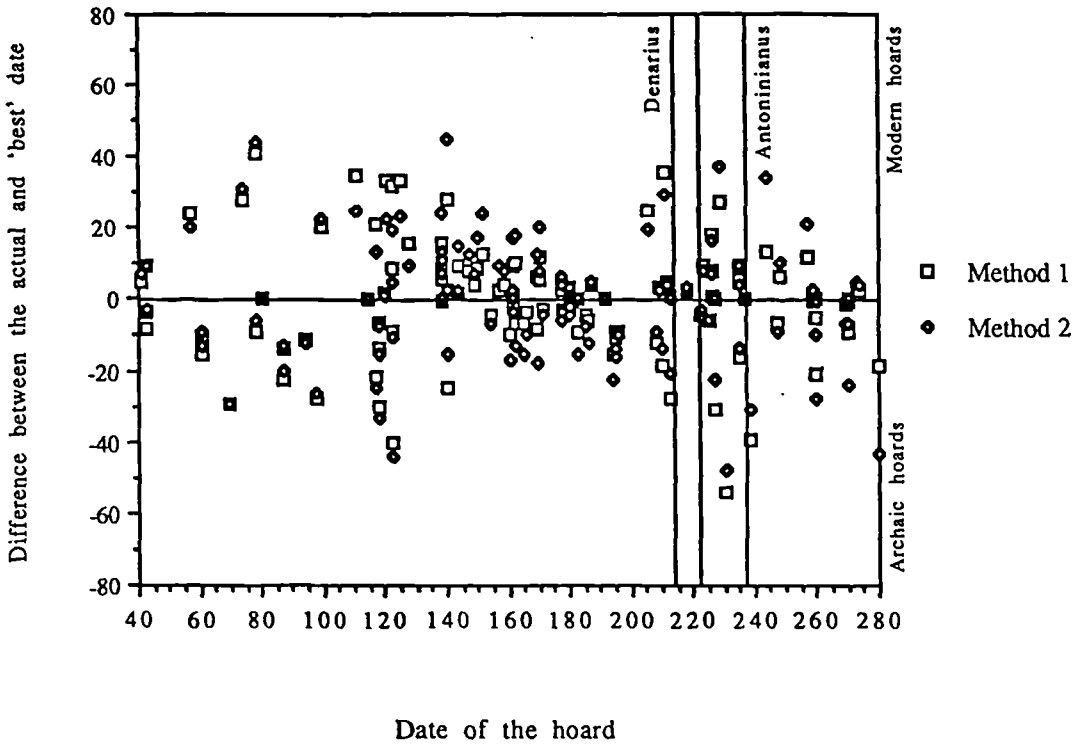

Fig. 45.06: The deviation (using both methods) of all the hoards against time

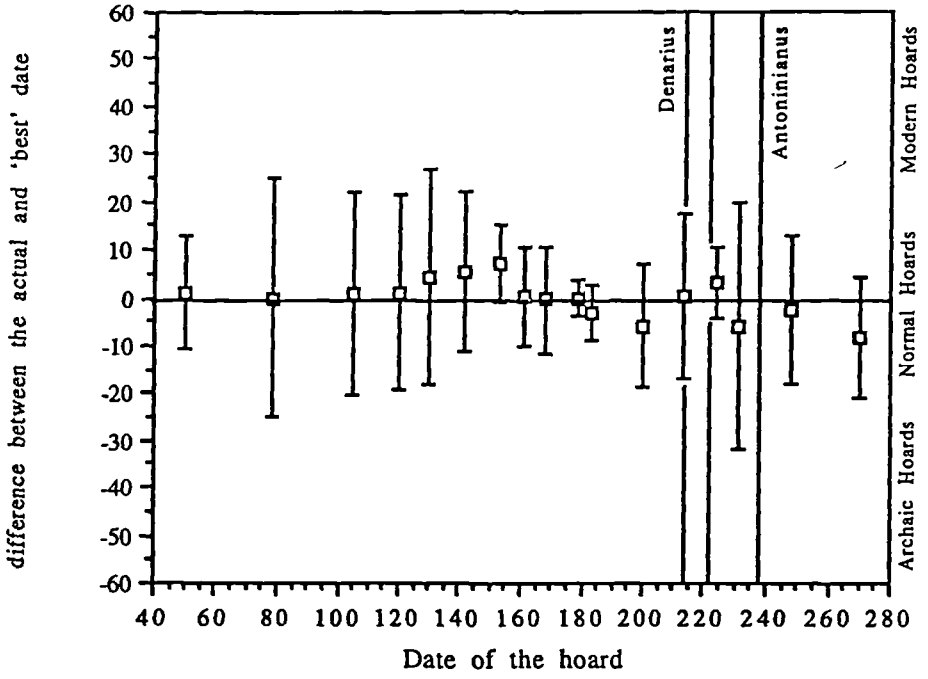

Fig. 45.07: The range of the deviation (using both methods) of hoards against time (1)

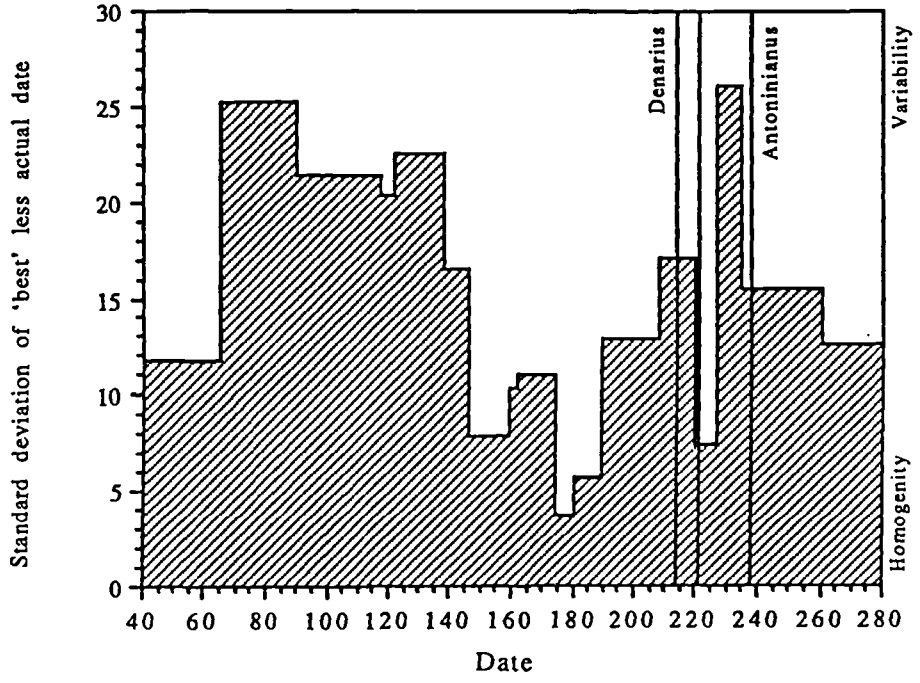

Fig. 45.08: The range of the deviation (using both methods) of hoards against time (2)

4.55 The calculation of Y, the number of transactions

We now have three variables representing the approximate shapes of (M) Money supply, (P) Prices and (V or $^1/_H$) Velocity of circulation. Once inserted into the equation it is a simple matter to establish the variable Y - the number of goods and services in the cash economy (Appendix 4.52). This is shown in fig. 45.09. As stated earlier, because of the nature of the variables inserted into the equation to generate this variable, only its grossest changes can be regarded as potentially meaningful. That being the case the graph may be described as follows:

Phase 1 A substantial number of transactions taking place immediately after the Claudian conquest

Phase 2 A period with very little activity during the later first century and into the very early second.

Phase 3 A period of sustained growth in the number of monetary transactions from the early second century to a peak in the 180s.

Phase 4 A decline in the number of transactions from the Antonine peak down to a low point in the mid third century when the number of *denarii* in circulation had dropped and significant numbers of *antoniniani* had not yet arrived to make up their numbers in circulation. One could hypothesis that had the data continued there might be a third peak in the late second century with the huge number of radiates in circulation, whatever speed at which they were circulating.

During the following interpretation of this graph various things must be borne in mind. First the early peak may be too short. This possibility has already been discussed for the *denarius* itself, but since the *denarius* supply figures here are meant to represent bronze coinage as well, the Neronian to Early Flavian peak in the *sestertius* curve should be considered. This would delay the trough's start from the Neronian period in fig 45.09 to c. AD 80 (cf. fig 42.07).

Secondly the graph is meant to represent any kind of transaction with coin, whilst this might be market trading, it could equally be bride-wealth or any other kind of social transaction. The equation would not distinguish between these.

Thirdly the number of goods and services traded within the cash economy might vary, not due to any changes in demand, but due to changes in the functions of money itself. One society might use coinage as bride-wealth, but this custom might disappear, leading

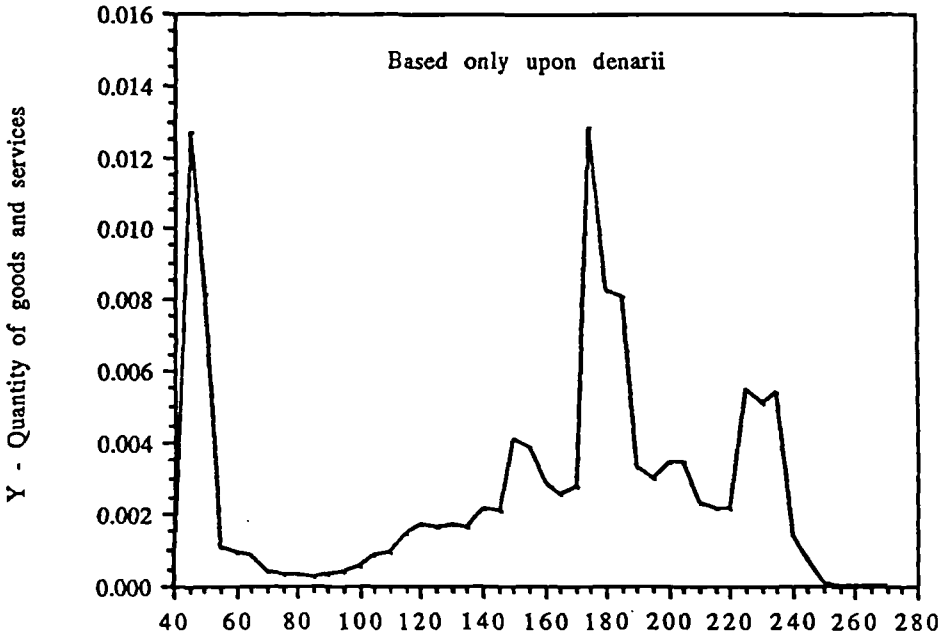

Fig. 45.09 (Y) A curve representing the changing number of goods and services with the Romano-British cash economy

to a decrease in the value of Y (which would potentially be inflationary). On the other hand new commodities, previously not within the monetary sphere, might be brought onto the market which would lead to an increase in Y (which could be anti-inflationary). Such changes are happening even today: in the last year of the USSR the economy was in a mess, lots of commodities were kept at artificially low prices for reasons of social policy. In the transition to a market economy one of the many proposed but aborted schemes meant that these artificially low prices would have to go, leading inevitably to price inflation. One way thought up of countering this was to increase the number of goods in circulation. Since there were no extra goods to be found something was needed which had not hitherto been considered a commodity. The suggestion was made that everyone should have to buy their own houses. This would increase Y and hence reduce pressure on the need for P(rices) to rise (Economist 31.3.1990, 71). The case is pertinent since Gregson (1982) has already suggested that the Roman period may see the conversion of land in Britain from a resource to a commodity. So changes in what money can buy would also effect the shape of the graph.

4.56 Interpretation and correlation with archaeological data

In discussing the archaeological evidence, especially pottery, it is the effect of imports and the military that will be looked at most. The military would have used coinage where making purchases outside the realm of taxation and requisition. Also whilst local ceramics may have been 'traded' through various social exchanges persisting from the LRPIA, imported vessels made closer to the heart of the empire would have been more likely to be traded for cash.

The Early Peak

Finding a peak in trading activity shortly after the Claudian conquest should not be at all unexpected. By AD 60/61 London had already developed into an important commercial centre flocking with traders (Tacitus *Annals* 14.33). This new foundation was not a centre based upon a pre-existing LPRIA central place constrained within a pre-existing social framework, and so the more extensive use of coin here for transactions in comparison to elsewhere would be likely. However, the goods were transacted many sites in the south rapidly received imported pottery and early brooches in the pre-Flavian period. This has been demonstrated in Sussex where samian arrived on many rural sites even earlier than the development of many of the towns:

> "...the arrival of samian ware in quantity fulfilled a demand stimulated by the shortage before the conquest. Its previous rarity had made it a prestige good, unavailable down the social hierarchy and so used to define position within society. The demand was sated by increased supplies after the conquest, so it reached more of the population for a short period before

> its very abundance removed from it any prestige of status value. Thus by the Flavian period it had passed the peak of its popularity on the rural sites of the south-east."
>
> (Millett 1990, 98)

This initial boom, as previously prestige goods flooded into the country, correlates well with the early peak in the model. Another site where the artifacts demonstrate extensive pre-Boudican trading is the Sheepen, Colchester. Here Sealey's (1985) analysis of the amphorae have shown there to be far more vessels from the pre Boudican deposits than either the LPRIA or later strata. However, it must be pointed out that later occupation on the site was minimal.

Interaction with the Roman Army in the South East and Midlands in this early period must also have promoted Roman monetary transactions through the spending of army pay and the contracting of army provisions. The letter above from Octavius in Vindolanda demonstrates that at a later date the Army certainly purchased some of their grain. This initial boom would not have lasted beyond the 70s when the Army moved further away and supplies would be sought nearer at hand. Whilst the database covers sites from the whole country it would still be fair to say it retained a south-eastern bias, so the army's passing presence in lowland Britain may have had an effect upon the curve.

Finally, of course, we have Claudius and Seneca's loans to Britain, which must have encouraged the use of Roman money up until their withdrawal around AD 60. Once again suggesting there should be an early peak in trading activity, perhaps receding after the Boudican revolt.

The Depression

It is not so easy identifying a depression in the archaeological record. One way is to look at the supply of pottery to the Roman Army. Swan (1984, 8) and Greene (1979, 99) state that the army's policy was to to obtain pottery locally as far as possible, to import small quantities of specialist wares where necessary, and to make its own pottery only as a last resort. If the graph represents the level of trading activity, then from the late first into the very early second century the Army may have had difficulty obtaining ceramics from the market place and may have had to resort to manufacture itself. In order to test this idea we have to demonstrate that both before and after this period the army was obtaining ceramics from the market, and only during this slump did it make pottery itself.

Swan (1984) sees evidence for this switch from the market to army manufacture in the late first century, and the change back in the 120s:

> "The pottery evidence suggests that in the Trajanic (97-117) period Roman official policy towards military supply changed radically .... A number of legionary and auxiliary depots was established for the manufacture of tiles and pottery, and these can be clearly distinguished on the Stanegate and elsewhere in the North. ... One effect of this was possibly to accelerate the decline of some of the earlier specialist industries such as the Kent mortarium manufacturers. ... Under Hadrian in c.AD 120, another drastic turn-about in military supply-policy is implied by the ceramic evidence. These depots were closed and the army of the North was left dependent on supplies from civilian sources further south, a policy seemingly adhered to thereafter. This must have contributed to the rapid expansion of the Dorset black-burnished ware industry and the Hartshill/Mancetter potteries, among others."
>
> (Swan 1984, 19)

Other evidence can be added to this. From the late first century into the second the Holt kilns supplied legion XX Valeria Victrix with tiles and pottery, while the IX Hispana apparently had kilns at York from the 70s to the end of the century (Breeze 1977,137).

However, it is not just the military supply and manufacture which demonstrates the possibility of a depression. Up until about AD 70, imported colour coated wares had been popular, but these are rare between then and the start of the large scale production in the Nene Valley in the 150s (Greene 1977, 125). Other imports suffered as well. Samian ware curves (Marsh 1981) also show this depression; from around AD 70 the level declined to reach a low point in the early second century, from which it began to rise again to a new peak in the 170s with the importations from Lezoux (Central Gaul).

Evidence exists from towns as well, most strikingly from Canterbury. Here, despite early activity, many of the areas of the town were covered by a grey loam during the last quarter of the first century through until AD 110-120. Whilst the theatre (and presumably associated temple precinct) was established around about AD 90, it cannot be said to have been sited within a thriving bustling commercial town. (Bennett 1991). A hint of this, though not so obvious, can be found at Verulamium. The shops of Insula XIV were not replaced after their destruction during Boudica's revolt until c.AD 75. When new buildings were built they were of a lesser quality and size; however c.105 they were rebuilt again though this time expanding to fill all the vacant space to the rear of the street (Frere 1983). The forum may have been built during the great depression, but this need imply nothing about the vitality of the monetary economy.

The Antonine Peak

It has already been noted that as the second century proceeds colour coated wares re-emerge in the 150s, Samian ware reaches a second peak in the 170s, and the army start receiving pottery from a series of expanding industries in the south from the Hadrianic period (117-138). This all seems to be in line with the gradual rise seen in the number

of transactions suggested from the low point in the late first century to a peak in the 180s. The fall thereafter continues until the mid third century. Some of the industries set up during this boom period can also be seen to die with it:

> "From c. 120 onwards, the regular shipping of black-burnished ware to the northern frontier along western sea-ways may well have stimulated the establishment or expansion of industries within easy access of such routes or along them, for example the Wilderspool, Cheshire, Muncaster, Cumberland, and Severn Valley potteries. Their distributions indicate a steady expansion in the number of potteries throughout the 2nd century, including more specialist factories than at any other time in Roman Britain. Many of these supplied relatively small quantities of their wares to the garrisons in Wales and the North. Most of them were relatively small and by the mid third century many had either ceased production or become of purely local significance."
>
> (Swan 1984, 19)

Evidence for this Antonine flourishing can be seen elsewhere, in villa construction for instance. Gregson (1982) has shown that it is at about AD 175 that the mean distance of villas from *civitas* capitals reaches its height (though the maximum number of villas was reached later). If villas relied upon the sale of their surplus through towns then the maximum distance of villas from towns must correlate with the healthiest period of interaction between the town and the villa. The Antonine boom would seem to be a reasonable context for this.

Beyond this date we have a decline into the mid third century, though quite possibly the sheer quantity of radiate *antoniniani* in circulation in the latter part may mean that there should be a peak here in the money-supply figures and thereby the Y-curve. However, this depends upon the degree to which a corresponding rise in prices counteracted this. Whilst prices rose from 250 to 270 (fig. 47.02), the graph shows that the major escalation in prices came just after 270 (fig. 47.01). Whilst this period is really beyond the scope of this thesis it might be that from 270 onwards we have a transfer from the use of coinage back to other forms of exchange. If people stopped using coin for transactions then Y would fall, hence all other things being equal the prices of the items still brought and sold for cash would go up. An inflationary cycle could have been entered into with even more people withdrawing from the monetary economy forcing prices up even further.

There appears to be some correlation between the archaeological evidence and the curve denoting the hypothetical number of monetary transactions taking place in exchange for goods and services. This certainly suggests that within the spheres of the military and imported pottery both were fully within a monetized economy. Without an analysis of the changing level of the production of coarse and local wares it is more difficult to say how far into the realms of other manufactured goods the use of money passed.

4.57 Economic growth and cyclical trends

One thing that is striking is that we do not seem to have a slow continuous 'monetization' as might have been expected. If anything the monetary economy could be seen as a series of booms and depressions, with peaks every 100 years or so, around the AD50s, 160s and the 260s. In this case the first short peak may entirely relate to the effect of the invasion. On the other hand it may be the second half of a boom which began earlier in the LPRIA. This kind of picture is contrary to the belief in sustained gradual economic growth in the late Republic and under the principate, a view epitomised by Keith Hopkins (1980) and in a slightly different version by Garnsey & Saller:

> "A general argument for economic growth under the Principate might run as follows: the accession of Augustus inaugurated an era of relatively stable government, the basic condition for economic recovery and expansion. The new regime was dedicated to the cause of civil peace and the pacification of Rome's enemies. The success of this policy furthered internal economic development, and insofar as it expanded the territory under Roman control, extended the economic horizons of the empire. ... Augustus lacked a clear and coherent policy of stimulating economic expansion, but he did create the conditions under which economic life could flourish. After his reign the pax Romana was by and large uninterrupted ... the empire suffered few major calamities until the middle of the third century."
>
> (Garnsey & Saller 1987, 51)

Instead of sustained growth we appear to have a series of booms and depressions in trading activity. Such cycles have long been discussed and almost taken for granted in more recent economic history, though that is not to say that the causes behind them have been understood (T. Hopkins & Wallerstein 1982). Various length cycles have been identified from the Kitchin cycle of 3-4 years, the Juglar cycle of 9-11 years and the Kondratieff cycle of 40-60 years, sometimes called 'long' cycles; then there are Cameron's 150-300 year cycles called 'logistics'. These cycles were originally identified as phenomena of features of the capitalist economy after the industrial revolution, but many historians have traced long cycles back in England into the 15th century, with 'logistics' going back into the 9th century, in each case with the cycle getting longer and longer. They only appear to stop there because the Economic Historian's data starts to become problematic at an earlier date.

In their discussion of cyclical rhythms within the context of world systems analysis, Immanuel Wallerstein and Terrence Hopkins (1982) pointed to a series of phenomenon which frequently occur during such cycles which potentially can be traced in Roman historical and archaeological sources:

1. During times of economic expansion there will be pressure towards ever greater specialization as the counterpart to ever greater interdependence within the economy. This would take the form of different areas of the Empire specialising in different goods and in the specialization of craft production. The reverse is the case during periods of contraction.

2. The effectiveness of the political machinery that guarantees the functioning of the social economy will vary. Since this has the power to restrain intra state social conflict and larger scale military conflict. Both constraints tend to be lessened during periods of stagnation.

These variables and suggestions regarding the supply and demand for goods manufactured in 'high wage cost' and 'low wage cost' areas of a system were deemed to vary in dual cycles labelled A1,B1 and A2,B2 ('A' being the expansion of the economy, 'B' being the subsequent contraction). During the first cycle one particular political power block would rise to dominate the 'world system', whilst during the second cycle it would decline eventually to be replaced by a new system. The predictions of the model are outlined below in Table 4.51.

Table 4.51:
Hopkins and Wallerstein's (1982, 112-120) predictions of phenomena during 'long period cycles'.

D(HW) = Demand for goods from High Wage areas
S(HW) = Supply of goods from High Wage areas
D(HW) = Demand for goods from Low Wage areas
S(HW) = Supply of goods from Low Wage areas

Cycle	Political Power	Social Structure	Specialisation	Trade & Production
A1 Rise	Ascending Hegemony Acute conflict between rivals to the succession		Increasing regional and craft specialization	D(HW) > S(HW) D(LW) > S(LW)
B1 Fall	Hegemonic victory 'New' power by-passes 'old' in decline	Social stress	Decreasing regional and craft specialization	D(HW) = S(HW) D(LW) = D(LW) Stagnation in LW areas earlier
A2 Rise	Hegemonic maturity True hegemony		Increasing regional and craft specialization	At the end of the rise: D(HW) < S(HW) D(LW) > S(LW)
B2 Fall	Declining hegemony Acute conflict of old power versus successors	Social stress	Decreasing regional and craft specialization	After this 'crash' Production in HW areas is particularly hit.

A superficial analysis suggests that the cycles indicated above for the first to third century Britain could be correlated with Hopkins and Wallerstein's suggestions. The first two cycles would be seen as the period of dominance of the Principate in the style of Augustus, the Flavians and the Antonines - the senator made king. This 'Hegemony' of the Early Empire was replaced after a crisis by the new order of the Late Empire, initially under the Tetrarchy, but then a new succession of Imperial Houses, but by this

time the nature and style of the office had radically changed, so had the structure of the Empire. The Late Empire would suggest a fourth boom in the mid to late fourth century. A money supply curve might indicate this with the re-emergence of large numbers of *siliquae* and the huge *aes* issues of the House of Valentinian (364-78). Table 4.52 is an attempt to draw together some of the historical and archaeological evidence to see if this kind of model fits the data. In it High Wage areas of production have been taken to be the extreme frontiers where there would have been more cash possibly leading to higher prices (cf. Birley 1981), eg. Germany and Northern Britain. Low Wage areas have been taken to be the areas described as 'tax exporting' regions by Keith Hopkins: Gaul and Spain:

Table 4.52: The Roman Empire and the Hopkins and Wallerstein model.

Cycle Phase	Political Power	Social stress	Specialization: Verulamium insula XIV	Production: the evidence of pottery.
A1 - Expansion ? - AD 55	Ascending Hegemony The establishment of the Principate and final expansion of the Empire		Phase 1 (49-60) Row of shops built early on, likened to military barracks	There is a high demand for both Gallo Belgic Wares (HW) and Southern Gaulish Samian (LW)
B1 - Stagnation AD 55-c.100	Hegemonic Victory		Phase 2a (c. 75-c. 105) After a gap building replaced by a lesser built construction	The demand for Southern Gaulish Samian Ware falls off (LW) as does the supply of Gallo Belgic Wares
A2 - Expansion AD 100-180	Hegemonic Maturity The establishment of Frontiers		Phase 2b-d (c. 105-150) Buildings expand to the rear to fill all the available space.	Demand for Central Gaulish (LW) Samian increases, but not Eastern Gaulish (HW) Samian, despite its closer proximity.
B2 - Stagnation AD 180-240	Declining Hegemony Problems with finances, problems with the succession		Insula XIV, having been destroyed by a fire, remains largely vacant	The production of central and eastern Gaulish samian both terminally decline into the 3rd century.
A1 - Expansion AD 240-280	Ascending Hegemony Acute conflict with the division of the empire and a high turn-over of emperors		The prize street frontage Wattling street is re-occupied by strip buildings in 275	Demand rises for products not from HW areas (Germany, N. Britain etc.) but from LW areas, especially southern Britain: eg. Oxfordshire, New Forest Wares.
B1 - Stagnation AD 280-340	Hegemonic Victory Establishment of the Tetrarchy and House of Constantine	Bacaudae in Eastern Gaul		
A2 - Expansion AD 340-370	Hegemonic Maturity	No references to bacaudae		Crambeck Ware (HW?) expanded after c.367, but the most important industries are those in the South (LW).
B2 - Stagnation AD 370-400+	Declining Hegemony Barbarian pressures and various usurpations	Bacaudae and stress on the frontiers.		Most of the major production centres enter into terminal declines

There is enough correlation to suggest that this form of analysis *may* prove useful in understanding structural changes in the Roman World, however more detailed archaeological investigations of other provinces (and the calculation of their money-

supply, velocity of circulation and Y curves) would be required which would be beyond the scope of this thesis. Incidentally the hegemony preceding the empire would be expected to have peaked around the mid second century BC, around about the time often described as the golden age of senatorial rule. In the opposite direction we have the 'victory' of a new hegemony from the late 5th to mid 6th century which matches with Clovis' (482-511) consolidation of the Frankish Kingdom, and its expansion into Burgundia, Thuringia and Provence under his sons. Thereafter the Frankish kingdom occasionally fell apart and was reconstituted, but the next great peak would be scheduled to arrive with the Carolingians around AD 800, the year Charlemagne was crowned Emperor in Rome.

4.58 And yet...

A headlong run into this form of analysis would be premature. The 'world system' view is based upon the existence of a reasonably integrated economic system. Though the level of political integration in the Roman world was certainly high, one may wonder about other aspects of the economy. The *denarius* was to all intents and purposes a universal currency in the central and Western Empire, but unless that currency and articles of trade were reasonably fluid how relevant is it to apply any of the 'world systems' terminology to the Ancient World?

Though some of the evidence above suggests that cycles did occur, they were certainly not empire-wide affairs. The floruit of the West seen in monumental buildings and levels of material culture appears as a mini dark-age in the archaeology of the East (cf. the evidence of the Boeotia Survey, Bintliff 1991). Though even within a confined area of the East these changes are not synchronous, the rises and fall of the Hellenistic floruit apparently being about 200 years earlier in SE Attica than in Boeotia. Even within the West the growth and decline of regional activities do not all appear synchronous, with Arretine Ware giving way to Southern Gaul, then Central and Eastern Gaul (though part of this might potentially be explicable in terms of the difference between high and low wage areas as the empire expanded and settled down).

In terms of other material culture the circulation of goods often appears to have marked regional tendencies. Duncan-Jones remarked upon this in his analysis of Roman Lamps in various provinces:

> "In so far as lamps were produced in the regions in which they have been found, the layout of finds still show regional limits in the way production was organised, which ultimately reflect limits in the long-distance trading pattern. The implicit boundaries, especially the sharp north-south differences within the western half of the empire, show limits in the trading pattern, and they do not support the view that, in trade terms, the empire formed a single integrated economy."
>
> Duncan-Jones (1990, 58)

Then there are the coins themselves. Walker (1988) remarked upon the provincial nature of bronze circulation. Certain types of *aes* rarely crossed certain boundaries like the Alps or the channel, this does not bode well for the concept of an integrated monetary economy. Kraay (1956) noted the even more restricted circulation of bronze coins with early imperial countermarks in the Rhineland. If this phenomenon were restricted to bronze it might not concern us too much, but Duncan-Jones has identified a similar pattern in the distribution of *denarii* across different provinces (1989b). The analysis is fairly restricted at the moment, but again it is suggestive of there being discrete regional economies within the framework of the empire as a whole.

4.59 Conclusion

This section has tried to bring together various elements of the analysis so far. Studying together the money-supply and velocity of circulation trends within the framework of the quantity theory of money the suggestion has been made that the economy in Roman Britain did not experience a continuous economic growth, rather after a rapid period of activity following the conquest of the south there was a depression lasting up and just into the beginning of the second century, a further recession began at the end of the Antonine period. This pattern has been shown to be not inconsistent with other forms of archaeological evidence.

Secondly we tried to see if these two peaks were part of a broader pattern within the context of broader economic trends in western Europe as a whole. Again a provisional investigation suggested that some of the predictions connected with cyclical trends in the economy can be traced in the evidence for western Europe (4.57). However, this part of the analysis is only suggestive as the chronologically and regionally restricted scope of this work is not sufficient to confirm such a picture on its own (4.58). Trends in one province should only very warily be taken to represent generalized pictures of what is happening elsewhere. Even if shown, the existence of cycles does not 'explain' what is happening. It just highlights systematic patterns which still need to be interpreted. Cycles should not be sought or studied for their own sake (eg. Going 1992).

'World systems analysis' (beyond the use of core-periphery phraseology) shows some potential for the investigation and interpretation of archaeological data, and numismatics has an important role to play here. Fisher's equation used with numismatic data has managed to produce at least an idea of the changing number of monetary transactions taking place within the Romano-British economy, and that pattern has been shown to be not inconsistent with other archaeological data. Were this work to be carried out in other provinces then a better idea of the workings of the empire as a whole could be achieved, and its level of integration assessed.

5.0 Concluding Remarks

In the introduction I set myself a series of questions to answer. Because Introductions are usually the last thing to be written to theses there is almost an inevitability that these have all been answered in one way or another. The first was 'How much money was there in circulation?'. A precise answer is impossible, but an idea as to changes in the quantity of money has been provided for both *denarii* (section 3.53) and *sestertii* (section 4.22) on the basis of a model of losses from the circulation pool. Other models based on wastage rates have been tried giving similar basic trends (section 4.23) and a reanalysis of Walker's Bath coin report has tagged some cautionary warnings onto his figures (section 4.21). So overall while no absolute quantification has come out of this, a 'feel' for the changing volume of silver and bronze in circulation has been achieved.

The second question was 'How evenly was this distributed?'. The answer depends upon a clarification of the question. In terms of the use of silver and bronze there was a slight tendency for areas to continue using similar metals to those used in that area in the LPRIA (section 4.13) for a generation at least. Thereafter in terms of the distribution of wealth, throughout the life of the *denarius* in Britain there appears to be a remarkable degree of stability in terms of the number of large to small hoards (2.63), perhaps suggesting a great deal of social stability. However, this might break down in the mid third century but that is really beyond the breadth of this work.

Thirdly, 'How rapidly did they circulate?'. Three methods were tried based on coin wear and the similarity of coin hoards (sections 2.36, 2.44 and 2.55). What all of them indicated was the variable rate of circulation which in previous analyses had always been assumed to be constant.

Fourthly, 'Where and how did coin enter circulation?'. We were able to show this in periods of slow circulation where the variability in hoard structures had a geographical pattern to it. Hoards containing greater proportions of new coin could usually be found where the army was located. But rarely at the Provincial capital - London (section 2.56).

Lastly, 'Was monetization progressive or variable?'. Here a minor digression is appropriate.

> "As in any self-sufficient pre-industrial economy, the bulk of the empire's labour force was primarily engaged in producing food, most of which the producers also consumed. This was the most important element of the Roman economy. We may add to this picture by assuming also that peasants individually grew most of their own food and did not exchange much produce with each other. In addition, it seems likely that handicraft workers, because of the low level of capital investment, each produced little

> more than the average peasant. We can now see that an extremely large proportion of all that was produced both in Italy and in the provinces was never traded; it stood outside the market, solid and inflexible, almost untouched by the forces of money. Analysis of the Roman economy has always to take that solid unmarketed core into account."
>
> (Hopkins 1978, 15-6)

The thesis has been almost entirely about money. Hopkins reminds us that it is all too easy to forget that the vast majority of food and work took place outside that monetary economy. That much exchange within the Roman Empire should not have used coin during certain periods should not surprise us. Strabo noted that in parts of post-Augustan Spain (the Lusitani and some of the northern tribes) barter in basic commodities such as goats milk, beer and butter was still practiced (as opposed to the more civilized cow's milk, wine and olive oil; Strabo, Geography, 3.3.7). But rather than being depressed at this the use of the quantity theory of money, if correct, could offer us a way of trying to examine the process of monetization. In section 4.5 an attempt was made to calculate 'Y', the number of monetary transactions taking place within Britain. It is just possible that all this curve reflects is the changing population level in the country: more people, more transactions; fewer people, fewer transactions. Yet such drastic changes in population level seem unlikely. The simplest explanation is that it reflects changes in the number of goods being transacted in the monetary economy and therefore the level of monetization of that society.

Perhaps the most important result is that monetization does not prove to be progressive all the way through until the sudden decline of Roman Britain, but rather cyclical. It starts off well, though its novelty wears off rapidly after the conquest leading to a depression lasting much of the late first and early second century. Hitherto the unyielding forces of 'progress' have all too often been taken for granted. The greater preponderance of later third and fourth century coin has been seen as facilitating the development of a market economy, and hence greater monetization:

> "...the bulk of exchange was ... embedded within social relations and was not solely for profit. The breakdown of this pattern, with an increase in buying and selling outside the sphere of social control in the later Roman period, has been argued to result from a reduction in the effective authority of the centralized élite, with the consequence that exchange was liberated (or became disembedded) from the social control so that the economy began to grow. This argument has been developed by Hodder ... and reinforced by Reece ... on the strength of the coin evidence. It has been shown that there was a massive increase in the number of coins *lost* from the third century onwards and these were of lower denominations than those of the early Roman period... . This evidence is consistent with a pattern of the increased *use* of coinage for exchange within a marketing system.
>
> (Millett 1990, 169; my italics)

Yet the coin evidence here may reflect no more than a difference between periods of instability in the financial systems where worthless coins were discarded and periods

when the monetary system was basically stable. 'Loss', the number of coins found on excavations, and 'use' are not the same thing. Also the presence of larger or smaller quantities of coin does not necessarily imply 'market conditions'. Large scale command economies can use vast quantities of money just as slightly freer 'market economies' (cf. the late Soviet Union vs. the West). Quantity of money and the existence of 'the market' are not necessarily linked. However, I hope this work has shown that by exploring the quantity theory of money we can at least develop ideas about the changing level of monetization, whatever that money was used for.

The Future

This thesis has been based upon the coins from one small part of the Roman world. There is no reason why the models should not be taken and applied to other provinces. Potentially we might be able to show how new coin circulated around the Empire as a whole. That would greatly enrich the arguments such as Hopkins (1980) about tax importing areas and exporting areas; as well as those who prefer to see more of the state interaction between provinces taking place by the procurement of taxation in kind (eg. Garnsey & Saller 1987). It is certainly into this wider area that this work should progress next. But that is just the numismatic side of things. The possibility of booms and slumps aired in 4.5 should also make field-archaeologists more aware of their interpretation of early Imperial levels. Until recently there was a reluctance in some quarters to see Roman towns in Britain as 'declining' from the third century onwards, though now recognized as a possibility and sought for, evidence appears to be turning up to support the idea. Similarly with the concept of a late first century to very early second century slump, given time and research similar patterns might be found at other towns than Canterbury and Verulamium, which are simply the two cases the author knows best.

Throughout this thesis an attempt has been made to develop numismatic models for drawing out patterning within the archaeological data. Those patterns still need to be interpreted. The interpretations which I have offered here may not be the correct ones, sometimes I myself have suggested alternatives, whilst I am sure readers will be able to come up with their own. However, agree or disagree with the interpretations, patterning has been shown within the data which needs to be explained. If this thesis has set anyone thinking about that then it has been worthwhile.

The hoards were:

1. Verulamium
2. Lancaster, Bridge Lane
3. Wheathampstead
4. Corbridge 1965
5. Thorngrafton
6. Lathom, Ormskirk
7. Brecon, Y Gaer
8. Birdoswald
9. Birdoswald
10. Dewsbury
11. Southants.
12. Corbridge 1911c
13. Weston, Green Farm

Appendix 2.21
Hoard Corpus

This corpus is divided into four parts:
1 Hoards from Northern Britain (Sekulla 1980)
2 Fourth century bronze hoards (Brickstock 1988)
3 Fourth century precious metal hoards (Archer 1979)
4 Additional hoards

Part 1: Coin hoards from Northern Britain
This is based on M. Sekulla (1980).
The format has been changed and the bibliography extended, corrected and updated where appropriate.

Appendix 2.22
Denarii in Coin Hoards

This appendix is divided into four parts. Part 1 contains summary information and details of denarii from Group D1 to D5; part 2 records D6-22; part 3 records D23-39 and part 4 records D40-57 denarii. The hoards are in chronological order. Italics denote copies. The value 0 denotes a missing data code.

Part 1; Groups D1 to D5

Appendix 2.23
The Number of Antoniniani in Coin Hoards

This appendix is divided into 4 parts. Part 1 contains summary information and details of antoniniani from groups A1a-3a; part 2 records A3b-11b; part 3 records A11c-19a and part 4 records A19b-27. The hoards are in chronological order. Italics denote copies where these can be identified. The value 0 represents a missing data code.

Part 1: Groups A1a to A3a

Appendix 2.24
Bronze coins in hoards

This appendix is divided up into three principle parts

Part A: Table of bronze coin hoards, their location, number and denominational contents.

Part B: *SESTERTII* IN HOARDS.
Here is the summary of the *sestertii* found in hoards. The termius post quem for each hoard may be derived from other coins within the the hoard. Sometimes bronze is describes as AE1, in which case this has been taken to mean *sestertii*. The raw data is given, with summaries (B1-3).

Part C: *DUPONDII & ASSES* IN HOARDS
Here is the summary of the 'middle bronze' coins found in hoards. The termius post quem for each hoard may be derived from other coins within the the hoard. Sometimes bronze is describes as AE2, in which case this has been taken to mean these. The raw data is given, with summaries (C1-3). In the summary tables *dupondii* and *asses* have not been distinguished.

PART A

Bronze coin hoards

Here are the principle hoards from the corpus which contain bronze coins. The terminus post quem for the hoard may be derived from other coins than the bronze component.

Appendix 2.31
Weight of Denarii in Hoards

This appendix is divided into two parts, firstly the summary statistics of the information, then the complete database from which they are derived.

Summary Statistics:

1. Hoard reference; 2. Hoard name; 3. Hoard TPQ; 4. Average coin weight; 5. Standard deviation of average coin weight; 6. Sample size; 7. 'Expected' average weight; 8. Deviation from expected weight

1.	2.	3.	4.	5.	6.	7.	8.

Appendix 2.32
Rates of wear of denarii

These figures are derived from the equations in Table 2.32
The individual group curves are displayed in Fig. 23.11
The average value is displayed in Fig. 23.12

This informationis used again in section 4.3 for the calculation of the silver content of the denarius circulation pool.

The values represent the average loss of weight every year of a denarius, on the basis of the sample of weighed coins found in hoards displayed in Appendix 2.31.

Group 1	Group 2	Group 3	Group 4	Groups 5-6	Group 7	Group 8	Group 9	Group 10	Date	Wear Rate

Appendix 2.41
Cumulative composition of denarii in coin hoards, expressed as a percentage

Italics denote copies. The values in brackets indicates the figure is based on missing data.

Part 1; Groups D1 to D8

Appendix 2.42
The average proportion of denarii in British hoards

The table shows the percentage of each coin group (A-Q) in hoards on average at five year intervals from AD 40 to AD 280. The values are based on interpolation (and for the AD 40-45 points extrapolation) from all hoards in the database containing more than five coins, and only including real denarii, copies have been excluded from the statistics (as far as possible).

Appendix 2.43
An introduction to Contingency Tables

Much of the following is based on Iman & Conover (1983, 302-311), using an example from the thesis.

A contingency table is an array of numbers in matrix form, where the numbers represent frequencies. For example the number of denarii found in coin hoards of the AD130's:

	Coin Series:				
	B-F	G	H	I-J	Total
Hoard 1	0	1	7	4	12
Hoard 2	18	22	65	33	138
Hoard 3	52	37	48	41	178
Hoard 4	13	15	19	15	62
Total	83	75	139	93	390

The data is represented by frequency counts O_{ij} in an r x c contingency table (one with r rows and c columns), where O_{ij} equals the number of observations (coins) in cell (i,j) - that is the intersection of row i with column j.

	Col 1	Col 2	Col 3	Col 4	Total
Row 1	O_{11}	O_{12}	O_{13}	O_{14}	R_1
Row 2	O_{21}	O_{22}	O_{23}	O_{24}	R_2
Row 3	O_{31}	O_{32}	O_{33}	O_{34}	R_3
Row 4	O_{41}	O_{42}	O_{43}	O_{44}	R_4
Total	C_1	C_2	C_3	C_4	n

Null Hypothesis: The classification by rows is independent of the classification by columns. This hypothesis requires individual interpretation for each application. In this case it says that each hoard (row) is and independent random sample of the circulation pool; hence the ratios of coin series (columns) 1 : 2 : 3 : 4 should ideally be the same in all cases.

In symbols:

H_0: $p_{ij} = p_i \times p_j$ for all cells (i,j)

Test Statistic: Let

O_{ij} = the **observed** count in row i, column j,

$E_{ij} = \frac{R_i C_j}{n}$

= the **expected** count in row i, column j, if the null hypothesis is true.

Then one form of the test statistic is:

$$T = \sum_{\text{all cells}} (O_{ij} - E_{ij})^2 / E_{ij}$$

Decision Rule. Reject the null hypothesis at the level of significance a if T exceeds the 1-a quantile of the chi-squared distribution with $(r-1)(c-1)$ degrees of freedom.

The table of data above therefore represents the O_{ij} values.

The values can be calculated by the equation above to be:

	B-F	G	H	I-J	Total
Hoard 1	2.5	2.3	4.3	2.9	12
Hoard 2	29.4	26.5	49.2	32.9	138
Hoard 3	37.9	34.2	63.4	42.5	178
Hoard 4	13.2	11.9	22.1	14.8	62
Total	83	75	139	93	390

(figures only accurate to 1 dec. place)

The next figures which needs calculating are the values of $(O_{ij} - E_{ij})^2 / E_{ij}$:

For example: For coin series H (c =3) and Hoard 2 (r = 2)

O_{23} = 65

E_{23} = 49.18

So: $(O_{ij} - E_{ij})^2 / E_{ij}$ = $(65 - 49.18)^2 / 49.18$ = 5.09

	B-F	G	H	I-J	Total
Hoard 1	2.6	0.7	1.7	0.5	5.5
Hoard 2	4.4	0.8	5.1	0.0	10.3
Hoard 3	5.3	0.2	3.8	0.0	9.3
Hoard 4	0.0	0.8	0.4	0.0	1.2
Total	12.2	2.5	11.0	0.5	**26.3**

(figures rounded up to one decimal place)

Since T is the sum of all the $(O_{ij} - E_{ij})^2 / E_{ij}$ values, T = 26.3.

Cramer's Contingency Coefficient (Φ)

Sometimes a **measure of association** in a contingency table is a useful descriptive statistic to obtain. There are many different measures that are used with contingency tables. Cramer's is widely used.

Let q = the smaller of r and c .

$$F = \frac{T}{n(q-1)}$$

Properties

1. Φ (capital 'phi') is a measure of association between the row classification and column classification in a contingency table.
2. Φ will tend to be close to zero, its minimum value, if there is independence between the row and column variables.
3. If all of the observations in each row tend to collect in one column, but in a different column for each row, Φ will tend to be close to 1.0, its maximum value.
4. Φ is the r x c analog of the phi-coeficient for 2 x 2 contingency tables. In fact , f equals squared if r = 2 and c = 2.

In the example above:
T = 26.3
r = 4 and c = 4, so q = 4
n = 390

So: $$\Phi = \frac{T}{n(q-1)} = \frac{26.3}{390(4-1)} = 0.0224$$

Since this value is very close to zero, it suggests that there is independence between the number of coins of a particular series and which hoard they are found in. That is to say, all the hoards are very similar in composition.

Appendix 2.44
Denarius Hoards: Contingency Tables

The tables are ordered in ten year time brackets starting from the AD 40's:

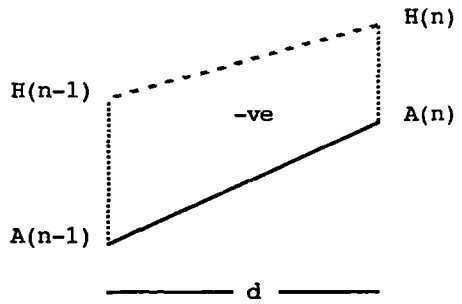
Appendix 2.51
Hoard structure analysis: the mathematical background

A(n) = the percentage of coins of up to emperor n in an Average hoard.
A(n-1) = the percentage of coins of up to emperor n-1 in an Average hoard.
H(n) = the percentage of coins of up to emperor n in the specific Hoard under analysis.
H(n-1) = the percentage of coins of up to emperor n-1 in the specific Hoard under analysis.
d = the number of years between the issues of n-1 and n

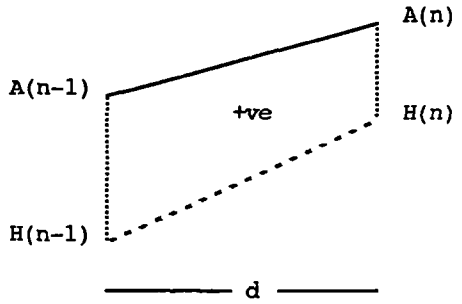
Case 1: An archaic segment



In this case the hoard has more older coins in it than would be expected on average. Therefore we want the computation to deliver a negative value to the area between these two dates. This is given by the following equation:

$$\text{Area} = \frac{([A(n-1)-H(n-1)] + [A(n)-H(n)])}{2} \times d$$

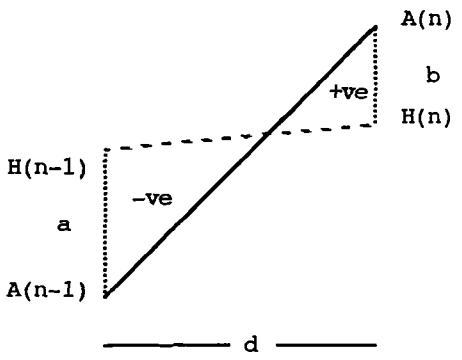
Case 2: An modern segment



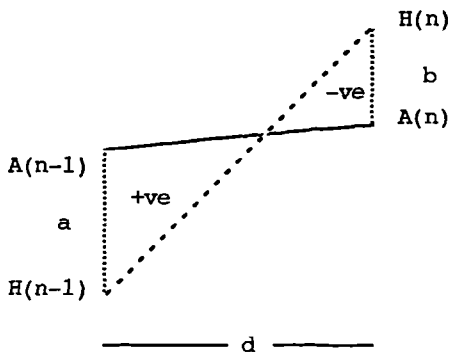
In this case the hoard has less older coins in it than would be expected on average. Therefore we want the computation to deliver a positive value to the area between these two dates. This is given by the following equation:

$$\text{Area} = \frac{([A(n-1)-H(n-1)] + [A(n)-H(n)])}{2} \times d$$

Case 3: A crossing segment



Case 4: Another crossing segment



Here there are both positive and negative areas which need to be calculated. The simple formulae used above will not suffice here, and a little bit of geometry is required.

Let us define the lengths *a* and *b*.

a = ABS(A(n-1) - H(n-1))
b = ABS(A(n) - H(n))

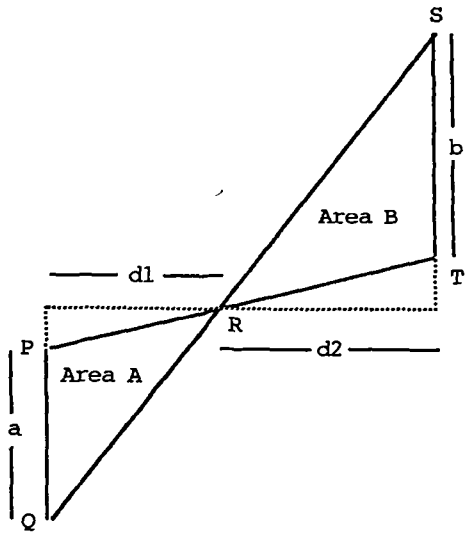
ABS is the absolute value; for example:
ABS(1.23) = 1.23
ABS(-1.23) = 1.23

Equation 1: $d = d1 + d2$

The triangles PQR and TSR are similar, therefore:

Equation 2: $\frac{a}{b} = \frac{d1}{d2}$

We need to find out the areas of PQR (Area A) and TSR (Area B)



Area A = $\frac{a \times d1}{2}$

$d2 = \frac{b \times d1}{a} = d - d1$ (from eq 1&2)

therefore: $\frac{b}{a} = \frac{d}{d1} - 1$

therefore: $1 + \frac{b}{a} = \frac{d}{d1}$

therfore: $d1 = \frac{d}{(1 + b/a)}$

So Area A $= \frac{a}{2} \times \frac{d}{(1 + b/a)}$

Area B = $\frac{b \times d2}{2}$

$d1 = \frac{a \times d2}{b} = d - d2$ (from eq 1&2)

therefore: $\frac{a}{b} = \frac{d}{d2} - 1$

therefore: $1 + \frac{a}{b} = \frac{d}{d2}$

therfore: $d2 = \frac{d}{(1 + a/b)}$

So Area B $= \frac{b}{2} \times \frac{d}{(1 + a/b)}$

Whether the value of Area A and Area B is positive or negative can be told from which is the larger, S(n) or A(n).

If S(n-1) > A(n-1) then Area A is -ve and Area B is +ve
If S(n-1) < A(n-1) then Area A is +ve and Area B is -ve

This being the case, it is now possible to find equations to calculate the area in all three cases above.

Computatons to calculate the net and gross area values

Based on the preceeding equations the following three routines together calculate the gross and net area values. The routines are written here as a simplified version of the actual version used, all unnessecary lines having been stripped in order to permit some clarity.

```
"Computations"
GrossArea = 0
NetArea = 0
FOR E = 2 TO 17
    A = Data(D,E-1) - Hoard(E-1)
    B = Data(D,E) - Hoard(E)
    C = A * B
    IF C>=0 THEN GOSUB "Normal Situation" ELSE GOSUB "Crossing Situation"
NEXT E
PRINT Index$, D, GrossArea, NetArea
RETURN
```

Notes: This routine decides which kind of case is being studied. If it is one such as case 1 or 2, where the specific hoard line and the average hoard line do not cross, then the routine "Normal Situation" is called. If the lines cross as in Cases 3&4, then the "Crossing Situation" routine is called. The ***FOR-NEXT*** *loop takes the calculations through all the issue series, from the Republican issues until the end; at each stage calculating the area between the two lines. At the end it prints the area value.*

```
"Normal Situation"
Area = (A+B) * (Dates(E)-Dates(E-1))/2
GrossArea = GrossArea + ABS(Area)
NetArea = NetArea + Area
RETURN
```

Notes: This routine calculates the area between the two lines between issue E and that immediately preceding it (E-1). The equation is the same as that above in cases 1&2.

```
"Crossing Situation"
AbsA = ABS(A)
AbsB = ABS(B)
AreaA = (AbsA*(Dates(E)-Dates(E-1)))/(2*((AbsB/AbsA)+1))
AreaB = (AbsB*(Dates(E)-Dates(E-1)))/(2*((AbsA/AbsB)+1))
GrossArea = GrossArea + AreaA + AreaB
NetArea = NetArea + (SGN(A)*AreaA) + (SGN(B)*AreaB)
RETURN
```

Notes: This routine calculates the area between the two lines between issue E and that immediately preceding it (E-1). The equation is the same as that above in case 3 & 4.

KEY

GrossArea	= The variable which represents the value of the gross area being calculated.
NetArea	= The variable which represents the value of the net area being calculated.
Area	= A variable representing the area between the line in cases such as 1 & 2 above.
AreaA	= A variable representing the area A in cases such as 3 above.
AreaB	= A variable representing the area B in cases such as 3 above.
Data(D,E)	= The average hoard composition: percentage of coins up to series E at date D.
Hoard(E)	= The specific hoard composition: percentage of coins up to series E present.
Index$	= The reference number of the specific hoard under analysis.
D	= The T.P.Q. of the specific hoard under analysis.
Dates(E)	= The date in calendar years at which coins of series E were issued.

Hoard structure analysis: worked examples

Examples of hoards with an archaic, modern and normal structure; & the Falkirk hoard

Notes

The **T.P.Q. range** is indicated by the latest coin from the hoard is marked by the date range between the two black lines.

The **'best fit date'** is indicated by a bold type-face.

The **best date within the T.P.Q. range** is indicated by the line being in italics.

A. An example of a normal structure

(with its 'best fit' date within its T.P.Q. range)

(C 179) Mildenhall(BeckRow)

This analysis is based on 277 denarii, which comprise all (if not nearly all) the denarii in the hoard. The TPQ date provided for the hoard is: 80-85AD

Date	TotalArea	NetArea
70	1459	1459

D. An example of a very archaic structure
(with its 'best' date outside its T.P.Q. range)

(S 071) Falkirk
This analysis is based on 931 denarii, which comprise all (if not nearly all) the denarii in the hoard. The TPQ date provided for the hoard is: 230AD

Appendix 2.53
Hoard structure analysis
Coin hoards with T.P.Q. ranges

Note:
The following tables show hoards which have not been given a precise T.P.Q.; because of this the 'best fit date' has been found calculated, and is highlited here. The definition is that point within the T.P.Q. band that the 'net area' tends most towards zero, i.e. it is neither archaich not modern in structure. In all subsequent analyses this has been used as the nominal date of the hoard.

(C 157) London (St Swithin's Lane)
This analysis is based on 89 irregular denarii, which comprise all (if not nearly all) the denarii in the hoard. The TPQ date provided for the hoard is: 41 - 54 AD

Reference	Date	Total Area	Net Area
C 157	41	1507	1507
C 157	42	1462	1462
C 157	43	1417	1417
C 157	44	1372	1372
C 157	45	1331	1331
C 157	46	1197	1195
C 157	47	1168	1134
C 157	48	1165	1047
C 157	49	1150	972
C 157	50	1189	915
C 157	51	1185	757
C 157	52	1256	596
C 157	53	1274	488
C 157	**54**	**1292**	**380**

(C 188n) Nunney
This analysis is based on 4 denarii, which comprise all (if not nearly all) the denarii in the hoard. The TPQ date provided for the hoard is: 43 - 54 AD

Reference	Date	Total Area	Net Area
C 188n	43	168	156
C 188n	44	132	96
C 188n	**45**	**95**	**55**
C 188n	46	126	-126
C 188n	47	220	-220
C 188n	48	364	-364
C 188n	49	459	-459
C 188n	50	508	-508
C 188n	51	747	-747
C 188n	52	891	-891
C 188n	53	1035	-1035
C 188n	54	1179	-1179

(C 241) Usk (Hoard 1)
This analysis is based on 6 denarii, which comprise all (if not nearly all) the denarii in the hoard. The TPQ date provided for the hoard is: 55 - 57 AD

Reference	Date	Total Area	Net Area
C 241	55	3078	3078
C 241	56	2902	2902
C 241	**57**	**2758**	**2758**

(C 103) Eriswell
This analysis is based on 72 denarii, which comprise all (if not nearly all) the denarii in the hoard. The TPQ date provided for the hoard is: 60 - 61 AD

Reference	Date	Total Area	Net Area
C 103	**60**	**1225**	**-1217**
C 103	61	1401	-1401

(C 221) Scole
This analysis is based on 87 denarii, which comprise all (if not nearly all) the denarii in the hoard. The TPQ date provided for the hoard is: 60 - 61 AD

Reference	Date	Total Area	Net Area
C 221	**60**	**1764**	**-1764**
C 221	61	1948	-1948

(C 260n) Weston Longville
This analysis is based on 2 denarii, which comprise all (if not nearly all) the denarii in the hoard. The TPQ date provided for the hoard is: 60 - 61 AD

Reference	Date	Total Area	Net Area
C 260n	**60**	**1448**	**-1092**
C 260n	61	1503	-1269

(C 128q) Honley (Northgate Mount)
This analysis is based on 13 denarii, which comprise all (if not nearly all) the denarii in the hoard. The TPQ date provided for the hoard is: 69 - 79 AD

Reference	Date	Total Area	Net Area
C 128q	**69**	**3379**	**-3379**
C 128q	70	3413	-3413
C 128q	71	3643	-3643
C 128q	72	3813	-3813
C 128q	73	4015	-4015
C 128q	74	4184	-4184
C 128q	75	4273	-4273
C 128q	76	4449	-4449
C 128q	77	4587	-4587
C 128q	78	4722	-4722
C 128q	79	4820	-4820

(C 036) Budge Row
This analysis is based on 74 denarii, which comprise only a partial sample of the hoards original contents. The TPQ date provided for the hoard is: 78 - 79 AD

Reference	Date	Total Area	Net Area
C 036	**78**	**1084**	**-1050**
C 036	79	1162	-1140

(C 179) Mildenhall (Beck Row)
This analysis is based on 277 denarii, which comprise all (if not nearly all) the denarii in the hoard. The TPQ date provided for the hoard is: 80 - 85 AD

Reference	Date	Total Area	Net Area
C 179	**80**	**383**	**59**
C 179	81	433	-87
C 179	82	492	-276

C 036s	**237**	**553**	**-29**
C 036s	238	567	-211

(C 058) Chesterfield

This analysis is based on 19 denarii, which comprise all (if not nearly all) the denarii in the hoard. The TPQ date provided for the hoard is: 238 - 244 AD

Reference	Date	Total Area	Net Area
C 058	238	2167	2167
C 058	239	2056	2056
C 058	240	2002	2002
C 058	241	1805	1805

C 058	243	1625	1625
C 058	**244**	**1541**	**1541**

(C 119) Great Chesterford

This analysis is based on 35 denarii, which comprise all (if not nearly all) the denarii in the hoard. The TPQ date provided for the hoard is: 247 - 249 AD

Reference	Date	Total Area	Net Area
C 119	**247**	**790**	**-790**
C 119	248	861	-861
C 119	249	930	-930

(C 124) Ham Hill (Montacute)

This analysis is based on 1 denarius, which comprise all (if not nearly all) the denarii in the hoard. The TPQ date provided for the hoard is: 270 - 273 AD

Reference	Date	Total Area	Net Area
C 124	**270**	**11589**	**-11589**
C 124	271	11639	-11639
C 124	272	11643	-11643
C 124	273	11661	-11661

(C 024) Bonnington

This analysis is based on 1 denarius, which comprise only a partial sample of the hoards original contents. The TPQ date provided for the hoard is: 270 - 273 AD

Reference	Date	Total Area	Net Area
C 024	**270**	**3839**	**-3839**
C 024	271	3889	-3889
C 024	272	3893	-3893
C 024	273	3911	-3911

(C 170) Market Deeping

This analysis is based on 11 denarii, which comprise all (if not nearly all) the denarii in the hoard. The TPQ date provided for the hoard is: 272 - 273 AD

Reference	Date	Total Area	Net Area
C 170	272	273	273
C 170	**273**	**257**	**257**

(C 128) Hollingbourne

This analysis is based on 2 denarii, which comprise all (if not nearly all) the denarii in the hoard. The TPQ date provided for the hoard is: 276 - 282 AD

Reference	Date	Total Area	Net Area
C 128	**276**	**276**	**-276**
C 128	277	280	-280
C 128	278	294	-294
C 128	279	294	-294

Appendix 2.54
Hoard structure analysis: basic results

Key:
1. The name of the hoard
2. The number of denarii studied
3. Full: the data comprise nearly all the denarii in the hoard, or Part: the data comprise only a sample of the hoard
4. The reference number of the hoard
5. The date or 'best fit within the TPQ range' date of the hoard
6. The gross area difference
7. The net area difference (positive is a modern structure, negative is an archaic structure). This is the **METHOD 1** result.
8. The 'best fit date' of the hoard against the AD40-280 'normal structure' benchmark devised
9. The gross area difference at the 'best fit date'
10. (Column 8)-(Column 5), the difference in date between the 'best fit' and actual date of the hoard (positive is a modern structure, negative is an archaic structure). This is the **METHOD 2** result.

Appendix 2.55
Hoard structure analysis: summary data

Two methods were used for this analysis. The first was based on the area of deviation on the cumulative composition graphs between the actual hoard and the 'normal' compositon of a hoard *at that date*. The second method was based on assessing what the 'best fit date' was for each hoard by seeing at which date 'normal' hoards had a most similar composition. The data from the two methods were then combined using the equation derived from Fig. 45.05. All three summary data sets are presented here.

METHOD 1: DATA

Date Range Range	Average net deviation from the 'normal' hoard	Standard deviation from this value	
41-78:	462	±2512	n=10
78-117:	163	±2361	n=10
117-122:	-37	±2851	n=10
125-140:	1094	±1859	n=10
144-160:	429	±774	n=10
161-169:	-18	±785	n=10
170-180:	187	±556	n=10
180-195:	-460	±664	n=10
195-213:	-102	±2243	n=10
218-229:	293	±1793	n=10
230-248:	-893	±2593	n=10
257-280:	-354	±1020	n=13

Data:

The values are in order of the dates of the hoards (cf. Appendix 2.54).
Hoards of irregular coins, hoards with less than five coins, and the Southants. hoard have been excluded. The hoards have been grouped in blocks of ten, except the last group which includes three extra.

METHOD 2: DATA

Date Range	Average deviation from the actual hoard date	Standard deviation from this value	
*41-87	7.0	±19.4 years	n=10 (excluding the 3 hoards)
41-87:	2.6	±19.6 years	n=13 (including the 3 hoards)
87-118:	-6.4	±20.7 years	n=10
118-138:	3.3	±21.6 years	n=10
138-147:	9.2	±15.3 years	n=10
149-161:	6.0	±12.1 years	n=10
161-171:	-0.7	±3.0 years	n=10
177-183:	-0.3	±3.9 years	n=10
183-196:	-7.3	±12.1 years	n=10
206-222:	-0.1	±13.5 years	n=10
223-235:	-0.2	±22.5 years	n=10
235-259:	1.6	±18.0 years	n=10
259-280:	-11.1	±15.6 years	n=10

Data:

The values are in order of the dates of the hoards (cf. Appendix 2.54).
Hoards of irregular coins, hoards with less than five coins, and the Southants. hoard have been excluded. The hoards have been taken in groups of ten.

*Note

Three early hoards have been excluded: Lightcliffe, Almondbury and Honley. In all three cases the 'best fit date' for the hoards was judged to be prior to 40AD. This being the case no data existed with which to compare its structure against. This means that the *differential* date between the actual and 'best fit' date can not be established; except to say that Lightcliffe is at least 3 years or more archaic, Almondbury is likewise, and Honley has a structure that is more than 29 years out of date. Because of this it should be remembered that the average value of the differential including or excluding these three hoards will be too high, and the standard deviation will be too small.

Appendix 2.61
Number of denarii in hoards: summary statistics

AD 41-60
Population: 37, 200, 200, 4, 6, 72, 87, 2
Mean = 76.0; $x\ s_{n-1}$ = 82.7; n = 8; Median = 54.5

AD 61-80
Population: 13, 35, 12, 14
Mean = 18.5; $x\ s_{n-1}$ = 11.0; n = 4; Median = 13.5

AD 81-100
Population: 277, 75, 32, 22, 20, 580, 32
Mean = 148.2; $x\ s_{n-1}$ = 211.2; n = 7; Median = 32.0

AD 101-120
Population: 197, 5, 49, 100, 100, 30, 40, 100, 125, 6, 60
Mean = 73.8; $x\ s_{n-1}$ = 57.5; n = 11; Median = 60.0

AD 121-140
Population: 9, 30, 28, 20, 26, 15, 7, 16, 12, 138, 178, 420, 5, 62, 280, 9, 300
Mean = 91.5; $x\ s_{n-1}$ = 127.7; n = 17; Median = 26.0

AD 141-160
Population: 600, 24, 39, 2, 100, 47, 33, 75, 40, 1000, 14, 12, 420, 6, 19, 82, 471
Mean = 175.5; $x\ s_{n-1}$ = 281.1; n = 17; Median = 40.0

AD 161-180
Population: 296, 16, 9, 27, 8, 9, 29, 920, 20, 20, 200, 70, 78, 38, 80, 35, 83, 61, 200, 75, 81, 28, 50, 368, 15, 13, 400
Mean = 119.6; $x\ s_{n-1}$ = 193.0; n = 27; Median = 50.0

AD 181-200
Population: 234, 296, 120, 433, 25, 155, 38, 180, 14, 100, 639, 190, 4, 600
Mean = 216.3; $x\ s_{n-1}$ = 208.0; n = 14; Median = 167.5

AD 201-220
Population: 2500, 8, 200, 6, 1476, 153, 350, 66, 500, 100, 33
Mean = 490.2; $x\ s_{n-1}$ = 789.7; n = 11; Median = 153.0

AD 221-240
Population: 59, 131, 32, 23, 548, 376, 9, 13, 3062, 29, 5, 5, 1931, 147, 480, 35
Mean = 430.3; $x\ s_{n-1}$ = 850.9; n = 16; Median = 47.0

AD 241-260
Population: 19, 224, 964, 35, 524, 16, 436, 753, 56, 664, 1, 29
Mean = 310.1; $x\ s_{n-1}$ = 344.3; n = 12; Median = 140.0

AD 261-280
Population: 14, 7, 1, 9, 5, 1, 11, 3, 1, 28, 2, 7
Mean = 7.4; $x\ s_{n-1}$ = 7.7; n = 12; Median = 6.0

Appendix 2.62
Size of Later Third Century Hoards

Here denarii have been included as half the value of antoniniani, and copies have been counted as of equal value. The reason for the latter decision being the frequent difficulty in distinguishing between the two in many reports.

Hoards from AD 230-265

Appendix 2.63
Denarius hoard size and location

Below are given all the hoards for which there is a reasonablly accurate idea of their original size. They have been divided up into period blocks, and within each of these into quartiles on the basis of hoard size. Their location has been given, together with a categorisaton into one of three regional zones. The three zones are defined as follows:

Zone 1:
Bedfordshire, Berkshire, Buckinghamshire, East Sussex, Essex, Greater London, Hampshire, Hertfod, Isle of White, Kent, Northamptonshire, Oxfordshire, Surrey and West Sussex
Zone 2:
Avon, Cambridgeshire, Dorset, Gloucestershire, Hereford and Worcester, South Humberside, Leicestershire, Lincolnshire, Norfolk, Nottingham, Somerset, Suffolk, Warwick and Wiltshire
Zone 3:
All other counties

Appendix 3.21
Site Finds: Summary Tables

All the sites within each category have been added together. The original database includes RIC references, where these were provided. They are not recorded here for reasons of economy of space.

The site categories are:

1. Cemeteries
2. Military sites
3. Rural sites
4. Small towns with forts
5. Small Towns
6. Temples
7. Urban sites
8. Villas

Appendix 3.22
Additional site list bibliography

The following sites do not appear in Ryan's database, therefore their sources are not published in Ryan (1988). Most of the lists are from northern sites to try and redress the bias of Ryan's site distribution.

Baldock	Rural	HERT	Baldock, the excavation of a Roman and pre-roman settlement, 1968-72. I.M. Stead & V. Rigby, Britannia Monograph Series No.7, 1986.
Castle Nick (Milecastle 39)	Military	NTHM	Unpublished listing, R.J.Brickstock 1988
Corbridge	Mixed	NTHM	Unpublished listing, P.J. Casey & R.J. Brickstock 1986
Cosgrove	Temple	NNTS	Unpublished listing, R.J.Brickstock 1989
Ilchester R10, R11, R2, R9	Urban	SOMS	Leech, R.H., 1982, Ilchester, volume 1, excavations; Bristol
Usk	Military	GWEN	Boon, G.C., 1982, Report on the Excavations at Usk 1965-1976: the Coins, Cardiff
Vindolanda Fort (1969-75)	Military	NTHM	Unpublished listing, P.J. Casey
Bewcastle (1937-78)	Military	CUMB	Unpublished listing, P.J. Casey
Piercebridge	Mixed	DURH	Unpublished listing, P.J. Casey & R.J. Brickstock
Wroxeter (3 lists)	Urban	SHRP	Wroxeter Palaestra 1968-86, provisional unpublished listing, P.J. Casey & R.J. Brickstock 1986; A furthe catalogue of coin finds from Roman Wroxeter, P.J. Casey & R.J. Brickstock 1987.
Aldborough	Urban	YORK	'The defences of Isurium Brigantium (Aldborough)', JNL Myres, KA Steer & AMH Chitty, Yorkshire Archaeological Journal, 40, 1959-62, pp 1-77.
Carrawburgh Fort	Military	NTHM	'Excavations at the Roman fort of Carrawburgh, 1967-1969', by D. Breeze, Archaeologia Aeliana 4th Series, 50, 1972, pp 81-144.
Catterick Fort	Mixed	YORK	'Cataractonium, fort and town', E W J Hildyard, Yorkshire Archaeological Journal 39, 1957, pp 224-65.
Ebchester Fort	Military	DURH	'Excavations at Ebchester Roman Fort 1972-3', V.A. Maxfield & A. Reed, Archaeologia Aeliana, 5th Series, 3, 1975, pp 43-104.
High Rochester	Military	NTHM	The coins from the excavations at High Rochester in 1852 and 1855', P.J. Casey & M. Savage, Archaeologia Aeliana, 5th Series, 8, 1980, pp 75-87.
Malton	Mixed	YORK	'Roman Malton: the civilian settlement', N. Mitchelson, Yorkshire Archaeological Journal, 41, 1963-6.
Rudston	Villa	YORK	'The Roman Villa at Rudston (E. Yorks): 4th Interim report: the excavations of 1936', K. A. Steer, Yorkshire Archaeological Journal, 33, 1936-7.
Sewingshields	Military	NTHM	'Sewingshields', D. Haigh & M. Savage, pp 33-147, Archaeologia Aeliana, 5th Series, 12, 1984, pp 33-147.
South Shields (1983-7)	Military	TYNE	Unpublished listing, R.J.Brickstock 1989
Turret 33b	Military	NTHM	'The excavation of Turret 33b (Coesike): the Coins' R.A.G. Carson, Archaeologia Aeliana, Series 4, 50, 1972, pp 145-78.
Wallsend	Military	TYNE	Unpublished listing, P.J. Casey & R.J. Brickstock 1987
York: Bedern	Urban	YORK	Unpublished listing, R.J. Brickstock
York: Bishophill	Urban	YORK	Unpublished listing, P.J. Casey & R.J. Brickstock
York: Blake Street	Urban	YORK	Unpublished listing, R.J. Brickstock
York: Cattle Market	Urban	YORK	Unpublished listing, R.J. Brickstock
York: Church Street Sewer	Urban	YORK	Unpublished listing, R.J. Brickstock
York: Clementhorpe	Urban	YORK	Unpublished listing, R.J. Brickstock
York: Coney Street	Urban	YORK	Unpublished listing, R.J. Brickstock
York: Coppergate	Urban	YORK	Unpublished listing, R.J. Brickstock
York: Coppergate ?	Urban	YORK	Unpublished listing, R.J. Brickstock
York: Ebor Brewery	Urban	YORK	Unpublished listing, R.J. Brickstock
York: Friends burial ground	Urban	YORK	Unpublished listing, R.J. Brickstock

York: Gillygate	Urban	YORK	Unpublished listing, R.J. Brickstock
York: Minster	Urban	YORK	Unpublished listing, P.J. Casey
York: Museum Chambers	Urban	YORK	Unpublished listing, R.J. Brickstock
York: Piccadilly	Urban	YORK	Unpublished listing, R.J. Brickstock
York: Skeldergate	Urban	YORK	Unpublished listing, P.J. Casey & R.J. Brickstock
York: St Mary's	Urban	YORK	Unpublished listing, R.J. Brickstock
York: Tanners Row	Urban	YORK	Unpublished listing, R.J. Brickstock
York: Trentholme drive	Urban	YORK	Unpublished listing, R.J. Brickstock
York: Union Terrace	Urban	YORK	Unpublished listing, R.J. Brickstock

Appendix 3.23
Site find emperor codes

These codes are based on Ryan's database. However as the database has been extended and refined further codes have become necessary. All additions to Ryan's coding have been indicated by an asterisk. Many of these insertions have been possible because gaps in the number sequence. Where gaps have not existed the next nearest gap has been used. This means that the codes are not given in acsolute chronological order. Other codes have been used for two type of coin. For example Ryan did not distinguish between Mark Antony and Republican coins, though many of these distinctions can be established using the catalogue references.

The columns below represent the code, the face on the coin, the code of the issuing authority and the Reece period.

001	REPUBLIC	001	1

Part 4: Bibliography

Macdonald, G. (1918)
Macdonald, G. (1924)
Macdonald, G. (1934)
Macdonald, G. (1939)
Robertson A.S. (1950)
Robertson A.S. (1961)
Robertson A.S. (1971)
Robertson A.S. (1983)

In all of these articles the finds are divided up into four groups, those from the Antonine Wall, from other 'Roman sites not on the wall', 'Native sites' and isolated finds. Only the first three groups from known sites have been used.

Appendix 4.11

The denominational structure of LPRIA monetary systems (after Haselgrove 1987)

The data is derived from Haselgrove (1987). The numbers represent the number of Mack entries in each series. As such a broad idea of the number of types and their spread across the denominations is arrived at. However it should be noted that there are several biases in this picture. Firstly some series are divided into more types than others owing to finer divisions rather than to there actually being more variation in the series. Secondly, no indication is given of the number of dies per type is given, and this may have varied greatly. Thirdly, the number of coins struck per die may have varied.

Appendix 4.12
Roman Coins in Iron Age Hoards

The data are from Haselgrove (1987) and Van Arsdell (1989). The corpus reference numbers for each hoard are given. The T.P.Q. have been assessed by the coin of Haselgrove's latest period within each hoard, as can be judged from the summary records. Those hoards recorded by Van Arsdell, but not by Haselgrove, have been converted from his reference system to Mack and thence to Haselgrove's periodisation. Appendix 4.11 gives the concordance between the Mack and Haselgrove classifications.

Appendix 4.22
Sestertius Supply Curve Data

Note: Unlike the denarius curve, this curve was constructed using only ten year intervals between dates, since it was thought the data would not stand more detailed analysis (the denarius curve used five year intervals). From c.AD 230 onwards the shape of the curve is problematic. See the text for further details.

Date	Value

Total	1143	

Example of part of one of the spreadsheets computating the number of sestertii in circulation on the basis of wastage rates. The extract only displays integers, though the calculations were done to 4 significant figures. The figures in italics represent the period of introduction of the issue. The rate of decrease here is 15% per annum.

1. Augustus, Agrippina & Germanicus (43)
2. Claudius & Antonia (43-54)
3. Nero (54-68)
4. Vespasian & Titus Caesar (69-79)
5. Titus & Vespasian Posth. (79-81)
6. Flavian (69-96)
7. Domitian & Domitia (81-96)
8. Nerva (96-98)
9. Trajan (98-117)
10. Hadrian, Sabina & L.Aelius (117-138)
11. Antoninus Pius, Faust. I & II M. Aurelius (138-61)
12. Faustina I or II (138-180)
13. Marcus Aureliu Faustina II & Lucilla (161-180)
14. Lucius Verus (161-169)

Appendix 4.31

Weight and silver content of denarii & antoniniani

Raw Data from Walker (1976, 1977 & 1978) and Crawford (1974)

Summary Data:		Number of Coins	Average Weight of Coin	Average Percentage of silver	Average Weight of silver
GROUP A	(REPUBLICAN)	35	3.65	96.52	3.52
GROUP B	(MARK ANTONY)	15	3.65	86.42	3.15
GROUP C	(JULIO-CLAUDIAN 1)	221	3.66	97.51	3.56
GROUP D	(JULIO-CLAUDIAN 2)	56	3.35	95.91	3.21
GROUP E	(CIVIL WAR)	84	3.23	93.04	3.00
GROUP F	(FLAVIAN 1)	213	3.20	90.59	2.89
GROUP G	(FLAVIAN 2)	171	3.24	93.34	3.02
GROUP H	(TRAJANIC)	275	3.22	90.49	2.91
GROUP I	(HADRIANIC)	365	3.20	88.90	2.85
GROUP J	(ANTONINE 1)	287	3.21	85.51	2.74
GROUP K	(ANTONINE 2)	222	3.23	79.75	2.58
GROUP L	(ANTONINE 3)	187	3.02	75.73	2.29
GROUP M	(SEVERAN 1a)	308	3.21	59.37	1.90
GROUP N	(SEVERAN 1b)	100	3.21	51.98	1.67
GROUP O	(SEVERAN 2a)	104	3.08	49.12	1.51
GROUP P	(SEVERAN 2b)	246	3.04	45.25	1.37
GROUP Q	(SEVERAN 2c)	37	2.93	51.95	1.52

GROUP A (REPUBLICAN)

35 coins from L.Iulius (224/1: 141bc) to P.Clodius (494/23: 42bc) have been taken to provide an average. This selection is somewhat artificial, and is unweighted (Crawford 1974, 570-1):

97.50	98.40	96.00	99.50	97.90	98.90	96.00	98.50
98.80	98.40	94.87	97.70	93.00	91.20	98.39	95.80
95.80	95.50	92.60	97.00	95.10	98.60	99.07	95.20
98.20	98.00	97.00	97.00	92.50	98.60	95.40	95.40
95.50	94.50	96.70					

Average = 96.52 % Silver

The weight standard was 3.86 g. (Crawford 1974, 594), however see the note below.

GROUP B (MARK ANTONY)

15 Coins of Mark Antony contained the following percentages of Silver (Crawford 1974, 571):

92.49	85.50	90.10	85.10	77.62	83.80	89.50	90.60
83.95	89.75	83.80	83.80	85.60	87.40	87.30	

Average = 86.42 % Silver

The weight standard was 3.86 g. (Crawford 1974, 595), however see the note below.

Note on the weight of the denarii of the Republic & Mark Antony:

Since all these coins were well worn before entry into Britian, a lower value than this is required. A lesser nominal, weight is therefore needed. Crawford pointed out that though the Legionary denarii were debased, they were still struck to the full Repubican weight. Therefore by looking at the weight of both these issues in hoards in Britain we should be able to arrive at a justifiable nominal 'issue weight' for their weight in AD43.

Chippenham	(Burnett & Bland, 1986, 2)	c.40s-50s?	3.62g
Scole	(Burnett & Bland, 1986, 7)	c.60/61?	3.54g
Eriswell	(Burnett, 1984, 6)	c.60/61?	3.55g
Mildenhall	(Burnett, 1984, 15)	c.80-85	3.45g
Howe (part 2)	(Burnett & Bland, 1986, 13)	c.87	3.24g
Howe (part 1)	(Burnett, 1984, 25)	c.87	3.23g
Cirencester	(Carson & Burnett 1979, 7)	c.94	3.33g
Londonthorpe	(Carson & Burnett 1979, 9)	c.154	2.40g

This data suggests that a nominal value of c. 3.65g for the weight of denarii of the Republic and Mark Antony would seem fair.

Later groups:

1. Emperor; 2. Approx date of issue; 3. Sample size;
4. Average weight; 5. Standard deviation of weight;
6. Percentage silver; 7. Standard deviation of percentage silver;
8. Weight of silver in coin.

Appendix 4.52
Silver in the circulation pool

Table 1: Walker's values for the percentage of silver in each series (See Appendix 4.31)

A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P	Q
96.52	86.42	97.51	95.91	93.04	90.59	93.34	90.49	88.9	85.51	79.75	75.73	59.37	51.98	49.12	45.25	51.95

Table 2: Weight of coins throughout their circulation life.

Each series starts at the weight observed by Walker (Appendix 4.31), and then declines at the rate calculated by the wear analysis. The rate of wear used is as recorded in Appendix 2.32, being the avarage rate of wear for all coin series. This information runs out at around AD 220 (where the rate was c. 0.012 gms pa.). For the years AD 225 to 239 this same rate has been used in default of any known value. However from AD 240 onwards no wear on denarii has been assumed. This means that the silver content from then on will be slightly over estimated as no assumed rate of wear is applied.

Table 3: Weight of silver in coins throughout their circulation life.

The values for the weights of the coins (Table 2) have been multiplied by the percentage silver in each coin series (Table 1) to calculate the weight of silver in each coin, at different stages in its circulation life. Naturally this diminishes as the coin is worn.

Table 4: The relative amount of silver in the circulation pool as a whole

Table 3 has calculated the amount of silver represented by one coin of any one issue throughout its circulation life. However different proportions of each issue were in circulation at different dates. The proportions are given in Appendix 2.42. The table below adjusts for this. For example, in the first period (nominally AD 40) 75.56% of the coins in circulation are Republican issues containing 3.523 gms of silver. There are also 7.41% early Julio Claudian coins with 3.154 gms of silver and 17.03% later Julio Claudian coins with 3.569 gms of silver in them. If a random sample from the circulation pool was taken and melted down, then the weight of silver per coin recorvered would be 3.503 gms of silver. This is the value shown in the last column. This is simply a weighted avarage, the weighting coming from the prportionas taken to be in the circulation pool from an analysis of hoard composition.

Appendix 4.51
Price Indices: Wheat, Wages and Army Pay

Table 1: Wheat prices

Data on wheat prices from Corbier (1978, 279) after J.P-. Callu, La Politique Financière des Empereurs Romains de 238 à 311, Paris, 1969, pp 395-396. The wheat is priced in sestertii.

Date	Price (HS)	Index
3	3	27
45	4	36
45	8	72
56	4	36
65	2	18
79	8	72
79	10	90
79	10	90
79	11	100
79	16	145
96	13	118
104	3	27
115	10	90
125	7	63
149	7	63
153	12	109
155	8	72
162	8	72
191	20 (Egypt)	181
191	18 (Egypt)	163
200	13	118
218	18	163
254	12	109
255	16	145
256	12	109
260	30	272
269	24	218
276	200	1818
293	300	2727
294	220	2000
301	666	6054
Index: AD 150 = 11 HS = 100 units		

Table 2: Wheat Prices from Palestine

Data from Daniel Sperver, Roman Palestine 200-400, Money & Prices. Ramat Gan, 1974, p 125 and 247. After West and Johnson, Currency, p 81; and Johnson in JJP, 4, 1950, p 156.

Date	Price	Index
1st Century	0.50 D	75
2nd Century	0.66 D	100
E 3rd Century	1.00 D	150
245-46	1.00-1.33 D	150-200
269	2.00 D	300
276	15.00 D	2250
293	23.00 D	3450
Index: AD 150 = 0.66 D = 100 units		

Table 3: Wages in Palestine

Data from same source as Table 2

Date	Price	Index
1st Century	1/6 - 2/3 D	20-83
2nd Century	1/2 - 1 1/3 D	62-166
Mid 3rd Century	1 - 1 1/3 D	125-166
Index: AD 150 = 0.8 D = 100 units		

Table 4: Burnett's index

Burnett 1987, pp 108-9.

Date	Index (1)	Index (2)
Second century BC	100	35
Caesar	200	71
Late 2nc c.	300	107
Gallienus 260	600	214
Index: AD 150 = c. 280 = 100 units		

Table 5:

Wheat prices from official transactions in Lower Egypt

from Duncan-Jones, Structure and Scale in the Roman Economy, 1990, pp153-154. Valuations in Drachmas per artaba.

Date	Price (drm)	Index
79	8	100
99	16	200
99	16	200
100	8	100
100-150 (125)	8	100
128	8	100
137	8	100
149	7	87
100-200 (150)	8	100
152	8	100
154	8	100
154	8	100
154	8	100
155	8	100
162	8	100
246	24	300
260-290 (275)	40	500
293	300	3750
294	220	2750
Price no. 50 has been excluded because the date is too imprecise.		
Index: AD 150 = 8 Drachmas = 100 units		

Table 6:
Wheat prices from private transactions in Lower Egypt
Data from Duncan-Jones, Structure and Scale in the Roman Economy, 1990, pp151-152. Valuations in Drachmas per artaba.

Date	Price (drm)	Index
18bc	9.3	78
16	9	75
45	4.4	37
45	5.7	47
45	8	67
45	8	67
45	8	67
